Preface

With this master thesis, my study in Department of Economics, University of Oslo ends. However, what I have learned and experienced here will become an invaluable treasure in my whole life. In this very moment, I want to thank all those who have helped me during my campus life.

First of all, I am deeply grateful to my two supervisors, Prof. Atle Seierstad and Prof. Tore Nilssen, for their great help, inspirational suggestions, insightful comments and constant encouragement.

I want to express my profound gratitude to Prof. Olav Bjerkholt and Prof. Finn Førsund who promote this program in China and grant us warm support and care in Norway.

I'm also grateful for all those lecturers who make economics an inspiring world to me. Thanks to for their wonderful lectures.

My thanks go to all the members of the Department of Economics for their assistance over my two-year study period, especially Prof. Kjell Arne Brekke, Ingunn Skjerve and Kaya Sverre.

I appreciate the tutoring by Prof. Zhu Ye at Fudan University for theoretical foundation and methodology in Corporate Governance, and great support and effort provided by my classmates.

Also thank all my friends and classmates here that make my life in Oslo enjoyable and memorable.

Finally, I want to thank my parents for their unconditional love and consistent support in my life.

Si Liu

Norway

Summary

This paper systematically presents theoretical and empirical research on board governance and earnings management of Chinese listed companies, trying to provide references for improving accounting information disclosure and corporate governance of listed companies.

The whole paper includes six chapters. The first chapter is the introduction and introduces the background and contributions, the innovations and research framework of my study.

The second chapter is the literature review on board governance and earnings management, in which I analyze and summarize existing literatures from different theoretical and empirical perspectives.

The third chapter measures the extent of earnings management of Chinese listed companies by using the Modified-Jones Model, which is based on the reviewing of measurement of earnings management and different research models.

The fourth chapter comprehensively evaluates board governance variables, namely, board size, board independence, board duality and board meetings by using descriptive statistics method.

The fifth chapter proposes theoretical hypotheses and conducts empirical examination on the relationship between board governance and earnings management of Chinese listed companies. In this chapter panel date model is introduced and Hausman test is conducted to determine which effect—fixed effect or random effect can better explain the regression model.

The sixth chapter is the conclusion and the main research findings are shown as follows:

1. Earnings management of Chinese listed companies

Among Chinese listed companies sorted by industries, 9 industries out of 12 exaggerate the profits through upward earnings management, 3 industries hide the profits through downward earnings management. Social Services Industry shows the highest earnings management level, while Communication and Culture Industry show the lowest earnings management level.

From 2002 to 2009, the average earnings management of Chinese listed companies gradually declined in fluctuation. The result indicates the quality of accounting information of Chinese listed companies has improved obviously in recent years.

2. Board governance of Chinese listed companies

The descriptive statistics of the four board governance variables show: the average number of board members in Chinese listed companies is 10; while the average number of independent directors is 4; only less than one tenth of Chinese listed companies have board chair also serves as CEO, and this situation tends to decrease.

3. Empirical findings on board governance and earnings management

By using Panel Data Model and controlling for corporate size, return on equity and other factors, the empirical findings on board governance and earnings management are:

- (1) Earnings management of Chinese listed companies is positively correlated to board size;
- (2) Earnings management of Chinese listed companies is negatively correlated with board independence;
- (3) Earnings management is negatively correlated to the separation of the roles of CEO and board chair.

1. Introduction

1.1 Thesis background and contributions

1.1.1 Thesis background

Institutional setting of Chinese stock market

The Chinese stock market was organized by the government as a vehicle for State Owned Enterprises (SOEs) to raise capital and improve operating performance (Green, 2003). Since the primary objective of developing equity markets is to help SOEs relax external financing constraints, regulations introduced have been asymmetrically in favor of SOEs or the companies with close ties to the government. A fundamental dilemma of the above administrative approach stems from the state policy of maintaining a full or controlling ownership in firms¹. The state wants the firms it owns to be run efficiently, but not solely for the purpose of wealth maximization, which creates conflicts of interest between the state as controlling shareholder and other shareholders. Even worse, the state is playing two roles at the same time—the controlling shareholder and the regulator (Clarke, 2003; Firth et al., 2006). The state representatives dominate corporate boards, which greatly compromise the independence of corporate boardrooms (Liu, 2006).

Tunneling in the Chinese listed companies

The Chinese institutional set-up in the stock market results in pervasive tunneling activities among the listed firms. In most cases, local governments appoint the management of listed firms. As a result, the management often takes action to benefit the largest shareholders (the local government in most cases). It is noted that such practice may add social values in other ways that offset the social costs it imposes through tunneling—e.g., it may help reduce external financing constraints and transaction costs. However, outside investors almost always lose when the

¹ The state takes direct control of important industries such as banking, energy and telecommunication

controlling shareholders tunnel (Cheung et al., 2005). Tunneling activities in China mainly take the form of granting loans to majority shareholders, and related-party transactions. A number of studies have examined the tunneling activities in the Chinese stock markets. Cheung et al. (2005) study a sample of related-party transactions between Chinese listed firms and their controlling shareholders. They provide evidence that related-party transactions are not typically beneficial for minority shareholders. Jiang et al. (2005) document the widespread use of corporate loans by controlling shareholders to extract funds from the listed firms in China.

Earnings management in the Chinese listed companies

Due to the administrative governance approach adopted in China, the regulators often rely on accounting numbers to govern the listed companies. the China Securities Regulatory Commission (CSRC) requires listed companies to meet certain return on equity (ROE) criteria before they can apply for permission to issue additional shares to existing shareholders. Therefore, listed firms have strong incentives to manage earnings above necessary thresholds.

Earnings management tends to be pervasive in China also because private benefits of control are large but the level of corporate governance is poor and the protection of minority investors is weak. To enjoy these private control benefits, controlling shareholders have strong incentives to manage earnings to avoid de-listing, especially when de-listing decision is relied on certain accounting numbers. To controlling shareholders and other insiders, being de-listed implies the loss of private control benefits and future rent-seeking opportunities. Therefore, doing whatever it takes to avoid net loss for three consecutive years provides the Chinese listed companies with another incentive to manage earnings.

1.1.2 Contributions

Enrich the research on board governance and earnings management of Chinese listed companies

Based on current stage of China's capital market development, this paper attempts to do systematic empirical research on board structure of listed companies and earnings management. We expect our research outcome can provide effective evidence for understanding board monitoring mechanisms will impose constraint on earnings management and enrich the research on board governance and earnings management.

Promote listed companies to improve board governance, effectively imposing constraint on earnings management, and improving transparency of listed companies' accounting information

We hope our research helps to understand the practical situation of board governance and earnings management of Chinese listed companies, in order to promote listed companies to improve board governance, effectively imposing constraint on earnings management, and improving transparency of accounting information of listed companies.

1.2 Innovations

Existing domestic empirical studies mainly focus on earnings management of listed companies in order to avoid regulatory constraints and market regulation. The studies aim to discover the motivation of earnings management of listed companies, and try to provide evidence for government regulation or provide references for the supervision of securities markets transactions.

On board governance side, the majority of articles study the impact of board structure on performance of listed companies. Systematic empirical research on board governance and earnings management is not sufficient, especially lacking the analysis of constraints on earnings management from each aspect of board structure. We will conduct in-depth research in this paper.

1.3 Research framework

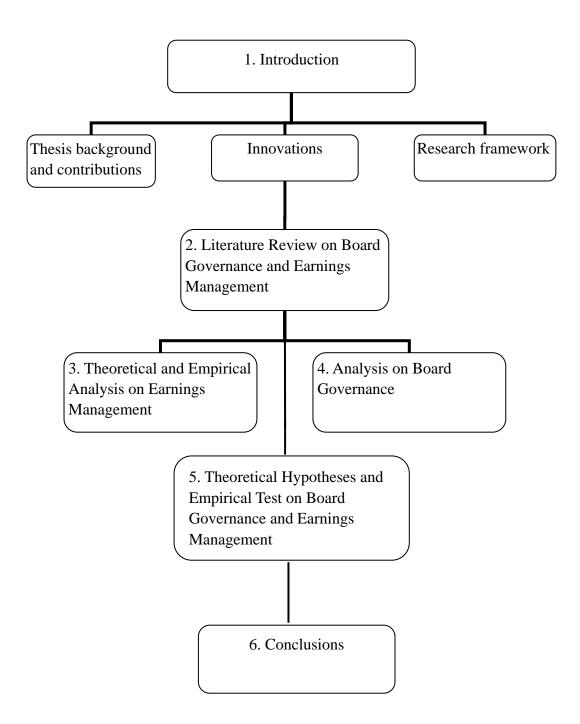

Figure 1: Research framework of board governance and earnings management of Chinese listed companies

2. Literature Review on Board Governance and Earnings Management

The prevalence of earnings management reduces the reliability of accounting information. Users may find it difficult to make fair assessment of corporate performance, managers' ability and effort based on earnings information. Worse still, it may mislead investors to make wrong investment decisions.

Board of Directors of listed companies exercises their monitoring functions to reduce earnings management in two ways: on one hand is to prevent managers from abusing their power against the interests of shareholders through earnings management; on the other hand is to prevent controlling shareholders from undermining corporate resources against the interests of minority shareholders for their own benefits. Therefore, board governance will impose effective constraints on earnings management.

2.1 Earnings management

A growing numbers of literatures abroad have examined corporate earnings management behavior in China's infant stock market. Aharony et al. (2000) identify evidence of earnings manipulation among the Chinese listed firms prior to their Initial Public Offers (IPOs). Chen and Yuan (2004) find that the Chinese listed firms manage earnings to satisfy the ROE requirements for rights issues. Jian and Wong (2005) present evidence that the listed manufacturing firms in China use related-party transactions to manage earnings. Chen et al. (2006) find that various aspects of corporate governance (e.g., boardroom characteristics and ownership) are associated with the incidence of corporate financial fraud.

Domestic researches on earnings management mainly focus on earnings management of listed companies in order to avoid regulatory constraints and market regulation. Lu Jianqiao (1999) takes the sample of listed companies facing losses before the end of 1997 and finds that these companies generally adopted earnings management to reduce or increase earnings in the loss year and the year before and

after, in order to avoid three consecutive year loss which will be regulated by securities regulatory authorities. Zhang Zongyi and Huang Xinjian (2003) conduct empirical study on IPOs of Chinese listed companies from 1998 to 2000 and find that there is significant earnings management in the listing year and the year prior to and after listing. Zhang Yanling and Peng Haoran (2004) empirical study on motivations of earnings management and earnings forecast error find that listed companies with over-estimated earnings will increase earnings through managing the operating income and working capital in the first year after listing, indicating there is strong motivation for listed companies to manipulate earnings in order to avoid punishment on earnings forecast error. Wang Yaping et al (2005) present evidence that from 1995 to 2003, there were earnings management by Chinese listed companies in order to avoid reporting loss.

2.2 Board governance

2.2.1 Board size and earnings management

The Board of directors has direct monitoring responsibility on the management, and obligations to impose constraints on earnings management. Board size (number of board members) is an important factor to the efficiency of board governance. A large number of empirical studies have provide evidence that there is relation between board size and corporate performance, but current studies do not give consistent research findings on the relationship between board size and corporate performance. However, empirical researches on board size and earnings management are rare.

Some scholars believe that to a certain corporate size, a too large board of directors cannot function to the best. This view is based primarily on the Agency Theory and Organizational Behavior Theory. Lipton and Lorsch (1992) present although board monitoring capacity increases with the number of directors increasing, the larger the board of directors, the severer is the free-rider problem (agency problem). The loss from coordination and organization will surpass the profit brought from increasing numbers of directors. Jensen (1993) indicates that the larger the board

of directors, the lower is the efficiency. The "hatred and revenge" between directors may weaken the board's monitoring and evaluation on CEO. While the board will be more easily controlled and influenced by CEO. Yermack (1996) identifies evidence from an empirical test. He takes "Fortune 500" companies as a sample and finds that a small board of directors is more efficient than a large one. Eisenberg et al (1998) take the sample of small and medium companies in Finland, and prove that there is a significant correlation between a smaller board of directors and higher firm performance. Wu (2000) studies changes in board size from 1991 to 1995. She finds that the overall size of board shows a reducing trend during this time, and the pressure from active investors can partially explain the phenomenon. She identifies that the market participants believe that small board of directors is doing better than relatively large board of directors in monitoring managers.

Resource Dependence Theory is the main theoretical foundation for the view that relatively large board of directors is more conducive to improve governance efficiency. More directors may bring more knowledge, experience and external resources to the board, making knowledge and experience within the board play complementary roles better, which to some extent reduces the company risk. In addition, it is easier to coordinate interests of different stakeholders in the board with different stakeholder representatives. Dalton et al (1999) present evidence based on the analysis of 131 different samples that there is significant positive correlation between corporate performance and board size, and the larger board of directors is able to provide better external resources and is more professional. Coles et al (2005) show that small board size does not apply to all kinds of companies, for those cross-industries, large-scale and high-debt companies, who need help and experience from more directors, board size and company performance are positively correlated.

From domestic perspective, Wang Liyan and Liu Junxia (2003) find that earnings management is negatively correlated with board size. Cai Ning (2003) finds that there is a significant positive correlation between board size and financial fraud.

2.2.2 Board independence and earnings management

From an agency perspective, the ability of the board to act as an effective monitoring mechanism is dependent upon its independence from management.

A large number of literatures abroad have conducted empirical research on independent directors' monitoring function on earnings management. Beasley (1996) finds that the presence of independent directors on the board reduces the likelihood of financial statement fraud. Klein A. (2002) suggests that boards structured to be more independent from CEO are more effective in monitoring the corporate financial accounting process and earnings management. Xie et al. (2003) finds that earnings management is less likely to occur in companies whose boards include both more independent outside directors and directors with corporate experience. But the level of earnings management may influence the subsequent selection of board. Davidson et al.(2005) find that, based on a broad cross-sectional sample of 434 listed Australian firms, a majority of non-executive directors on the board are significantly associated with a lower likelihood of earnings management. Peasnell et al. (2005) examines whether the incidence of earnings management by UK firms depends on board monitoring. Results indicate that the likelihood of managers making income-increasing abnormal accruals is negatively related to the proportion of outsiders on the board. Cornett (2009) finds that earnings management and corporate governance are endogenously determined. Thus, OLS estimation can lead to biased coefficients and a simultaneous equations approach is used. Based on 593 largest bank holding companies head-quartered in US, the paper indicates earnings, board independence, and capital are negatively related to earnings management.

From the domestic point of view, Zhang and Chen (2006) shows that the higher percentage of independent directors in the board, the lower level of earnings management, which suggests independent directors of Chinese listed companies are playing an important role. Zhang et al. (2006) indicates there is a significant "U" shaped relationship between the proportion of independent directors and earnings management.

However, Cai (2007) indicates that there is no significant correlation between independent directors and earnings management. Wang (2007) tests the relation between independent directors and earnings quality based on the listed companies' data from 2002-2004. The result is, in general, independent directors have not performed an efficient role yet in China.

2.2.3 Board duality and earnings management

Board duality, that is, whether the chairman of the board is the same person as general manager, is the focus of academic debate. **Modern Stewardship Theory** argues that chairman of the board and general manager should be the same person. Boyd (1995) points out that this mode helps to improve the efficiency of communication and decision-making.

However, Agency Theory actively advocates chairman of the board and general manager should be different persons. In order to prevent moral hazard and adverse selection problems generated by managers, an effective monitoring mechanism is necessary. If the manager is the same person as the chairman, then the monitoring mechanism will collapse. Lipton and Lorsch (1992), Jensen (1993) suggest that chairman and general manager is the same person will lead to a low efficient board, because the board would be difficult to carry out its monitoring function. Dechow et al (1996) find that if the board is controlled by general manager, earnings management is more likely to occur. Beasley (1996) points out, CEO serves as chairman of the board will lead to power concentration and conflict of interests, thus undermine board monitoring function.

From domestic view, CEO serves as chairman of the board is often seen as hindering corporate performance improvement. However, it has not yet reached a clear conclusion that chairman and general manager is the same person will increase the possibility of earnings management. This paper will conduct empirical research in this area in order to clarify the relation between board duality and earnings management.

2.2.4 Board meetings and earnings management

The frequency of board meetings may reflect whether the board is active or not. It is generally believed that an active board is more effective in monitoring the management, so decisions made are more in line with the interests of majority shareholders, thus is conducive to enhance corporate performance.

Lipton and Lorsch (1992) suggest that increasing board meeting time will improve the efficiency of the board. The more frequent board meeting is, directors are more willing to perform their duties which are consistent with the interests of shareholders. On the contrary, Jensen (1993) finds that most of the board meetings are not very effective. The board is often forced to engage in high-frequency activities to resolve corporate matters. Therefore, a higher frequency of board activities may be the response to poor corporate performance.

The literature on board meetings and earnings management are rare and mainly from abroad. Vafeas (1999) finds that the more frequent the board meeting, the lower degree of earnings management and the more transparency is corporate financial information. Xie et al (2003) suggest that board meeting is an important factor to restrict earnings management activities of managers.

2.3 Literature review summary

From the above literature review, we find there are few papers making profound theoretical and empirical analysis on the relationship between board governance of Chinese listed companies and earnings management. And the relevant empirical studies show quite different results. So in the following parts, we will first give theoretical and empirical analysis of earnings management in Chinese listed companies, then followed by examination on the relations between board governance of Chinese listed companies and earnings management.

3. Theoretical and Empirical Analysis on Earnings Management

The setting up of corporate board is to coordinate the conflicts of interest between shareholders and managers, aimed at maximizing the shareholders' interests by dispensing constraints and incentives to managers. Therefore, a perfect governance structure of the board will compress manager's implementation space of earnings management and manipulation.

In this part, we will first study the quantitative analysis of earnings management through reviewing and summarizing the existing quantitative research models, and then by comparing the models, we will determine a suitable model for earnings management measurement of Chinese listed companies.

3.1 Measurement of earnings management

Theorists have been attempting to deliver an accurate and objective measurement for earnings management in order to do a better quantitative research. The existing measuring models of earnings management can be divided into three categories: accruals model, specific accruals model and accruals distribution model.

3.1.1 Accruals model

Accrual model is currently the mainstream measuring of earnings management. This method points out that total accruals of a listed company is composed of accruals by earnings management, namely discretionary accruals, and accruals by different accounting methods, namely non-discretionary accruals. Therefore, from measuring non-discretionary accruals by constructing a regression model, discretionary accruals is calculated as the difference between total accruals and non- discretionary accruals, which measures the degree of earnings management.

3.1.2 Specific accruals model

As accrual method depends on some subjective assumptions, there is some limitation in practical application. Researchers choose to study accruals models case

by case and put forward the specific accruals model. They try to make analysis and calculation of specific accrued items to determine the degree of earnings management. But the drawbacks of specific accruals model often confines to a small sample or specific industry, which makes the research results impossible to popularize.

3.1.3 Accruals distribution model

Accruals distribution model is a more practical method. This method firstly need to determine specific earnings index, then through testing distribution of reporting earnings around the specific index to judge the existence of earnings management. Existing researches find that around specific earnings index, there are more or less observations than expected, indicating around these specific earnings index earnings management exists. But the shortcoming is that by using this method, one cannot get the information on means and degrees of earnings management hence cannot further do a quantitative study.

3.1.4 Measurement of earnings management

According to existing empirical researches home and abroad, we find that accruals models get the most extensive applications in quantitative study of earnings management, and the theoretical research on earnings management through accruals model is relatively mature.

In this paper, we will conduct empirical test on the relationship between board structure and earnings management, so quantitative measurement of earnings management is necessary. In addition, the realized quantitative measurement should support large sample. In this respect, accruals model has the advantage over the other two models, therefore we will adopt accruals model for measuring earnings management.

3.2 Earnings management models under accruals method

Healy (1985) suggests that the net income of firms can be divided into two parts: operating cash flow and accruals, and notices that accrued items can change the confirming time for reported earnings and allow managers to transfer earnings between each period. The measurement of earnings management under accruals model is based on decomposition of total accruals (TAC) into non-discretionary accruals and discretionary accruals. Non-discretionary accrual is calculated through regression model and discretionary accrual is the difference between total accruals and non-discretionary accruals, which is a measure of earnings management. By reviewing existing research on earnings management models, representative econometric models basically are as follows:

3.2.1 Jones Model

Jones (1991) relaxes the assumption that non-discretionary accruals can only be constant numbers and puts forward an earnings management model aimed at controlling the influence of economic environment change on non-discretionary accruals. The model calculating non-discretionary accruals is demonstrated below:

$$NDA_{t} = a_{1}(1/A_{t-1}) + a_{2}\Delta REV_{t}/A_{t-1} + a_{3}PPE_{t}/A_{t-1}$$

Where:

 \triangle REVt = change in sales revenue between year t -1 and t,

PPEt = gross property, plant and equipment in year t,

At - 1= total assets at the end of the previous year t-1,

a1, a2 and a3 are industry-specific coefficients estimated from the following cross-sectional regression:

$$TA_{t} = \alpha_{1}(1/A_{t-1}) + \alpha_{2}\Delta REV_{t}/A_{t-1} + \alpha_{3}PPE_{t}/A_{t-1} + V_{t}$$

Where α_1 , α_2 and α_3 are the OLS regression estimates of a1, a2 and a3 respectively, TAt = total accruals in year t divided by total assets in year t-1.

A hidden hypothesis of Jones model is that sales revenue cannot be manipulated. But if earnings management is realized through manipulation of sales revenue, then the model will make the part of earnings management removed from discretionary accruals.

3.2.2 Industry Model

Dechow and Sloan (1991) present industry model which also eases the assumption that non-discretionary accruals are constants as Jones model does. But the difference is that industry model assumes that influence factors of non-discretionary accruals are the same between different enterprises in the same industry. Industry model is as follows:

$$NDA = r1 + r2 \text{ median } (TA)$$

Where median (TA) is the median of total accruals divided by total assets in year t-1, r1 and r2 are industry-specific coefficients estimated from OLS model.

Industry model eliminates the difference of non-discretionary accruals within different enterprises in the same industry, but if the changes of non-discretionary accruals are rendered by enterprise specific environment factors, the industry model cannot separate non-discretionary accruals and discretionary accruals accurately.

3.2.3 Modified-Jones Model

Assume account sale also can become a source of earnings management. Dechow (1995) presents Modified-Jones Model by deducting accounts receivable from sales revenue. The model is as follows:

$$NDA_{t} = a_{1}(1/A_{t-1}) + a_{2}(\Delta REV_{t} - \Delta REC_{t})/A_{t-1} + a_{3}PPE_{t}/A_{t-1}$$

Where, $\triangle RECt$ = change in accounts receivable between year t -1 and t, industry-specific coefficients a1, a2 and a3 and non-discretionary accruals come from the original Jones Model.

So the only adjustment of Modified-Jones Model is that it deducts change in accounts receivable from change in sales revenue. The underlying assumption is that all the change in accounts receivable is caused by earnings management. This is based

on the following reasoning, for managers, it is much easier to manage earnings from accounts receivable than from cash sale income.

3.3 Earnings management of Chinese listed companies

3.3.1 Modified-Jones Model for earnings management

From Chinese listed companies operating situations and accounting procedures, corporate non-discretionary accruals will definitely change with the economic environment. Although the original Jones Model is trying to explain the influence of economic environment change on non-discretionary accruals, it does not take into account that different industries have different influence factors on non-discretionary accruals of the listed companies. And if most of non-discretionary accruals changes are caused by enterprise specific environment factors, then the industry model, which ignores differences in enterprises within the same industry, cannot separate non-discretionary accruals and discretionary accruals accurately. To sum up, we will adopt the Modified-Jones Model to measure earnings management in Chinese listed companies.

$$EDA_{t} = TA_{t}/A_{t-1} - \left[a_{1}(1/A_{t-1}) + a_{2}(\Delta REV_{t} - \Delta REC_{t})/A_{t-1} + a_{3}PPE_{t}/A_{t-1}\right]$$

Where:

 \triangle REVt = change in sales revenue between year t -1 and t,

 \triangle RECt = change in accounts receivable between year t -1 and t,

PPEt = gross property, plant and equipment in year t,

At - 1= total assets at the end of the previous year t-1,

a1, a2 and a3 are industry-specific coefficients estimated from the following cross-sectional regression:

$$TA_{t} = \alpha_{1}(1/A_{t-1}) + \alpha_{2}(\Delta REV_{t} - \Delta REC_{t})/A_{t-1} + \alpha_{3}PPE_{t}/A_{t-1} + v_{t}$$

Where α_1 , α_2 and α_3 are the OLS regression estimates of a1, a2 and a3

TAt = NetIncomet - CFOt,

Where CFOt = Net Cash flow from operating activities in year t.

3.3.2 Sample selection

Due to measurement of earnings management need to differentiate research samples of various industries, we differentiate various industries according to *Industry Classification of Listed Companies Guidelines* issued by China Securities Regulatory Commission.

Our empirical test are conducted using data for all the listed firms in Shanghai Stock Exchange (A Share) with fiscal year ends between 2001 and 2009 as a primary sample, making the following screening:

- 1) Eliminating listed companies in financial and insurance industry, because compared with other sectors, companies in financial and insurance sector have special accounting rules;
 - 2) Removing all ST companies;
 - 3) Removing companies with incomplete financial data between 2001 and 2009.

In order to make a comprehensive research on earnings management of Shanghai A-share listed companies, same number of listed companies are selected as samples from each industry, and altogether 93 listed companies are finally chosen, covering 12 industries (see table 1 below):

Table 1: 2001-2009 Shanghai Stock Exchange 93 A-share sample companies sorted by industry

Data source: Wind database (Shanghai A-share Companies financial statement data)

3.3.3 Empirical test and results on earnings management

We adopt SUR (Seemingly Unrelated Regression Models) to conduct empirical test on the following model:

$$TA_{t} = \alpha_{1}(1/A_{t-1}) + \alpha_{2}(\Delta REV_{t} - \Delta REC_{t})/A_{t-1} + \alpha_{3}PPE_{t}/A_{t-1} + v_{t}$$
(1)

Regression results for parameter α_1 , α_2 and α_3 can be found in Appendix, where:

$$ta_assi = TA_t/A_{t-1}$$

 $drvci = (\Delta REV_t - \Delta REC_t)/A_{t-1}$
 $ppei = PPE_t/A_{t-1} \quad (i = 1.2...., 93)$

The results show that the model is significant, hence indicates modified-Jones model can estimate sample enterprises' non-discretionary accruals.

According to the following equation:

$$EDA_{t} = TA_{t}/A_{t-1} - \left[a_{1}(1/A_{t-1}) + a_{2}(\Delta REV_{t} - \Delta REC_{t})/A_{t-1} + a_{3}PPE_{t}/A_{t-1} \right]$$
(2)

The expected discretionary accruals are residuals from the above regression (1), thus we can come to the conclusion that measurement results of discretionary accruals (EDA) of the above 93 companies are shown in Table 2.1-2.12.

Earnings Management of Companies in Mining and Quarrying Industries

From the table below, we can see from 2002 to 2009 there are 33 observations in Mining and Quarrying Industries with negative earnings management (EDA), meaning the enterprises made downward earnings management to hide profits by manipulating discretionary accruals, and the maximum extent is -0.11; while another 31 observations showing positive EDA, indicating sample enterprises made income-increasing earnings management by increasing discretionary accruals, and the maximum extent is 0.10.

During observation period the average earnings management of sample companies is 2.36E-07, showing that the whole industry executed an upward earnings management.

Earnings Management of Companies in Communication and Culture Industries

From the table below, we can see from 2002 to 2009 there are 16 observations in Communication and Culture Industries with negative EDA, meaning the enterprises made downward earnings management, and the maximum extent is -0.10; while another 24 observations showing positive EDA, indicating enterprises made income-increasing earnings management and the maximum extent is 0.07.

The enterprise which made the maximum upward and downward manipulation in earnings is CHINA TELEVISION MEDIA LTD.

During observation period the average earnings management of sample companies is 2E-07, showing that the whole industry executed an upward earnings management.

Earnings Management of Companies in Power, Gas and Water Production and Supply Industries

From the table below, we can see from 2002 to 2009 there are 33 observations in Power, Gas and Water Production and Supply Industries with negative EDA, suggesting the enterprises made downward earnings management, and the maximum extent is -0.34; while 31 observations showing positive EDA, indicating enterprises made income-increasing earnings management, and the maximum extent is 0.40.

Both the upward and downward earnings management is greater than Mining and Quarrying Industries and Communication and Culture Industries. The annual earnings management of SHANGHAI ELECTRIC POWER CO., LTD. is the highest in the industry.

During observation period the average earnings management of sample companies is 6.25E-09, suggesting that the whole industry executed an upward earnings management.

Earnings Management of Companies in Information Technology Industry

From the table below, we can see from 2002 to 2009 there are 34 observations in Information Technology Industry with negative EDA, suggesting the enterprises made downward earnings management, and the maximum extent is -0.34; while 30 observations showing positive EDA, indicating enterprises made income-increasing earnings management, and the maximum extent is 0.59.

The earnings management of SHANGHAI EAST-CHINA COMPUTER CO., LTD, and FUJIAN START GROUP CO. LTD. is relatively high in the industry.

During observation period the average earnings management of sample companies is 4.69E-09, suggesting that the whole industry executed an upward earnings management.

Earnings Management of Companies in Manufacturing Industry

From the table below, we can see from 2002 to 2009 there are 34 observations in Manufacturing Industry with negative EDA, suggesting the enterprises made downward earnings management, and the maximum extent is -0.14; while 30 observations showing positive EDA, indicating enterprises made income-increasing earnings management, and the maximum extent is 0.17.

The earnings management of LAO FENG XIANG CO., LTD. and NINGBO SHANSHAN CO., LTD. is relatively high in the industry.

During observation period the average earnings management of sample companies is 8.67E-19, suggesting that the whole industry executed an upward earnings management, but with tiny level.

Earnings Management of Companies in Integrated Industry

From the table below, we can see from 2002 to 2009 there are 31 observations in Integrated Industry with negative EDA, suggesting the enterprises made downward earnings management, and the maximum extent is -0.22; while 33 observations showing positive EDA, indicating enterprises made income-increasing earnings management, and the maximum extent is 0.18.

During observation period the average earnings management of sample companies is 3.25E-07, suggesting that the whole industry executed an upward earnings management.

3.3.4 Summary on earnings management of Chinese listed companies

To sum up, through reviewing theoretical and empirical research on earnings management, we adopt Modified-Jones Model to measure the earnings management of sample companies, and at the same time made an effective analysis on the trend of earnings management. The main research findings are summarized as follows:

Earnings management in different industries: firms from 9 industries out of 12 exaggerate profits by increasing their discretionary accruals, firms from 3 industries make downward earnings management to hide profits; among them, sample companies in Social Services Industry show the highest earnings management level. The whole industry made downward adjustment on discretionary accruals to hide profits; firms in Communication and Culture Industry show the lowest earnings management level. The whole industry made an upward adjustment on discretionary accruals to exaggerate profits.

Trend in earnings management: from 2002 to 2009, the average earnings management of 93 sample companies gradually declined in fluctuation. The result shows that the overall earnings management level of listed companies is declining, and the accounting information quality of Chinese listed companies has seen an obvious improvement in recent years.

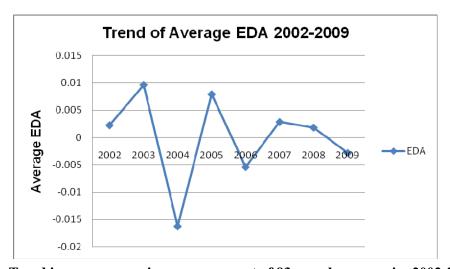

Figure 2: Trend in average earnings management of 93 sample companies 2002-2009

4. Analysis on Board Governance

As the board is not directly involved in the daily operation and management of the firm, its impact on firm's earnings is indirect. The governance structure of the board may affect the effectiveness of its role as decision-making and monitoring, which will indirectly affect the earnings management behavior.

In the circumstances that other factors affect earnings management equally, in the company where the board could effectively monitor managers and shareholders, earnings management behavior can be controlled. Managers cannot abuse their power, and controlling shareholders cannot transfer resources for their private benefits. So the degree of earnings management will be lower than the company lack of effective monitoring mechanisms. Thus better board governance structure will constrain earnings management to a greater extent.

4.1 Board governance variables

Through literature review and analysis on board governance structure, we introduce four variables: board size, board independence, board duality and board meetings, to evaluate the monitoring function of the board.

Based on samples selected for measuring earnings management of Shanghai A-share listed companies in previous chapter and the availability of board governance data², we narrowed our observation period to fiscal year ends between 2006 and 2009, and collected sample data on number of board members, number of independent directors, whether chairman and CEO is the same person and board meeting frequencies for the above four variables.

² Board data are hand-collected from annual reports of Chinese listed companies.

4.2 Explanations of board governance variables and descriptive statistics

Board Size (LN_DN): number of board members disclosed in annual reports of sample companies, including chairman, vice chairman, directors and independent directors. We will adopt the same measurement of board size proposed by Yu Dongzhi and Chi Guohua $(2004)^3$, namely, for company i, board size is described as the logarithm $LN(DN_{ii})$ of board members DN_{ii} (excluding honorary director or chairman, candidates of directors and board advisor) disclosed in the annual report in year t. Table 3 shows that the minimum number of board members in sample companies is 5, and the maximum is 20. The average number of board members is 10.

Table 3: Descriptive statistics of board size from 2006 to 2009

| Variable | Mean | Std. Dev. | Min | Max | Observations |
|----------|----------|-----------|----------|----------|--------------|
| DN | 10 | 2.302167 | 5 | 20 | N=372 |
| | | | | | T=4 |
| | | | | | n= 93 |
| LN_DN | 2.295233 | 0.2240569 | 1.609438 | 2.995732 | N=372 |
| | | | | | T=4 |
| | | | | | n= 93 |

Note: n=number of sample companies; T=observation year; N =n*T

Board Independence (IND): number of independent directors employed by listed companies during the reporting period according to the disclosed information in annual reports, denoted as IND_{it} . Table 4 shows that the number of independent directors in sample companies is up to 10, low to 1, and the average number is 4.

³ Yu Dongzhi and Chi Guohua (2004) "board size, stability and Corporate Performance: Theoretical and empirical analysis" [J], Economic Research, Vol.4.

Table 4: Descriptive statistics of board independence from 2006 to 2009

| Variable | Mean | Std. Dev. | Min | Max | Observations |
|----------|------|-----------|-----|-----|--------------|
| IND | 4 | 0.9421543 | 1 | 10 | N=372 |
| | | | | | T=4 |
| | | | | | n= 93 |

Note: n=number of sample companies; T=observation year; N =n*T

Board Duality (DUA): according to the disclosed information in annual reports of sample companies, if chairman of the board and general manager is the same person, then DUA=1, otherwise DUA=0. Table 5 indicates that in the 93 sample companies, only less than one tenth of the companies whose chairman also serves as general manager, and this situation tends to decrease in the observation period.

Table 5: Descriptive statistics of board duality from 2006 to 2009

| Variable | 2006 | 2007 | 2008 | 2009 | Observations |
|----------|------|------|------|------|--------------|
| DUA=1 | 9 | 6 | 6 | 7 | n= 93 |

Note: n =number of sample companies

Board Meetings (MEET) / individual characteristics of the board: according to the disclosed information in annual reports of sample companies, board meetings is calculated by deducting meetings held by means of communication from the total board meetings during the reporting period. Due to these specific features of the company generally cannot be fully reflected in companies' annual reports, it will be regarded as unobservable variable α_i .

5. Theoretical Hypotheses and Empirical Test on Board Governance and Earnings Management

In order to prove the role of the board as monitoring and constraining earnings management, we will conduct empirical test on the relations between board governance and earnings management of Chinese listed companies, where board governance can be measured through board size, board independence, board duality and board meetings.

5.1 Theoretical hypotheses

5.1.1 Board size and earnings management

A large body of academic literature from China and abroad have proved that board size, namely the number of board members, plays an important role in board monitoring efficiency, and also significantly influences earnings management of enterprises. But current studies do not draw consistent conclusion.

Some research find that a smaller board is more efficient, because communication and coordination between board members is much easier, and a small board can react to the problems in daily operation more quickly. While other studies suggest that a large board can offer better external resources, and by attracting more directors with business management experience and extensive finance knowledge into the board, the decision-making of the board will be more professional. A smaller board is likely to be controlled by internal management, leaving the board out of power. While a larger board will bring in more outside directors, which will reduce the level of internal control and increase board independence, thereby the board will play an effective monitoring role. Based on the analysis above, the following hypothesis is proposed:

H1: Earnings management is negatively associated with board size, namely, the larger the board size, the lower level of earnings management.

5.1.2 Board independence and earnings management

The purpose of introducing independent directors to the board is to further improve corporate governance structure, and to better regulate listed companies' operations. Increasing the proportion of independent outside directors in the board can reduce the level of internal control and increase board independence, thus help the board better fulfill its responsibilities. This leads to the following hypothesis:

H2: Earnings management is negatively associated with the independence of the board of directors, namely, the more independent directors in the board, the lower level of earnings management.

5.1.3 Board duality and earnings management

To some extent, whether the chairman and general manager is the same person reflects board independence. According to agency theory and transaction cost theory, in the case that chairman and general manager is the same person, the opportunistic behavior of managers and the agency loss will increase. Also there will be conflicts between two different functions, which make it difficult to protect the benefit of shareholders and other stakeholders. A large number of domestic and foreign empirical studies have proved that the board with chairman serves as general manager is difficult to impose effective monitoring on management. And China Securities Regulatory Commission (CSRC) regards the separation of the roles of chairman and CEO as an important method to improve corporate governance. Therefore, we test the following hypothesis:

H3: Earnings management is negatively associated with the separation of the roles of CEO and board chair, namely, the separation will reduce the level of earnings management.

5.1.4 Board meetings and earnings management

Board meetings mechanism is also one aspect of general concern in theoretical studies on board governance. Current studies have not reached consistent conclusion on the functions of board meetings. However, considering the reality of China's capital market, when the inside managers manipulate the earnings, they naturally want to reduce or distract the concern of such matters from outside directors, and reducing the frequency of board meetings is an effective way. Because the more frequent of board meetings, the more chances of board members vote on matters involving earnings management; contrarily, the fewer board meetings, its members may not pay attention to such matters. Therefore, the higher frequency of board meetings may reduce earnings management. This leads to the following hypothesis:

H4: Earnings management is negatively associated with board meeting frequency, that is, the higher frequency of board meetings, the lower level of earnings management.

5.2 Empirical test on board governance and earnings management

5.2.1 Panel data model

In order to examine the above hypotheses, we setup the following regression model taking earnings management as explained variable, board size, board independence, board duality and board meetings as explanatory variables, to test the impact of board governance on the extent of earnings management.

After controlling for corporate size LnCSIZE (logarithm of year-end total assets), return on equity ROE (net income/ equity) and other factors, we should notice that board size, board composition and board duality may be endogenously determined by earnings management, firm performance and other variables. If we conduct OLS

regression without considering endogenous variables, there will be a large bias in the model. Therefore, we will use Panel Data Model to solve the endogenous problems of unobservable variables in company board.

Panel Data Model is set as follows:

 $EDA_{it} = \alpha_0 + \alpha_1 LNCSIZE_{it} + \alpha_2 ROE_{it} + \alpha_3 LNDN_{it} + \alpha_4 IND_{it} + \alpha_5 DUA_{it} + \alpha_i + \mu_{it}$ Where,

i = 1, 2,, 93, denotes 93 sample listed companies in Table 1; t=2006, 2007, 2008, 2009, denotes observation years;

 α_i denotes the features of each board that is independent of time, i.e. unobservable characteristics of the board

In order to be consistent with observation years of board governance variables, we adopt EDA data from 2006 to 2009 in Table 2.1-2.12.

Generally speaking, panel data is estimated according to fixed effect and random effect. A Fixed Effect Model is estimated by least squares dummy variable (LSDV); while a Random Effect Model is estimated through feasible generalized least squares (FGLS) (Greene, 2000). Both of them can greatly take the advantages of panel data, and minimize the estimation error. As for which model should we use, it will depend on the results of Hausman Test.

According to Panel Data Model, α_i features of each board that is independent of time, is difficult to be quantified or directly observed in most cases. Thus it will be explained from fixed effect and random effect.

5.2.2 Fixed effect model

First, we adopt fixed effect model⁴ of static panel data. In fixed effect model, individual features are reflected in specific intercept for each firm. By taking α_i , features of each board as intercept, we get the estimated results as follows⁵:

$$EDA_{it} = -0.048978 - 0.008895LNCSIZE_{it} - 0.002715ROE_{it} + 0.126085LNDN_{it} - 0.012877IND_{it} + 0.050883DUA_{it}$$

$$(-4.4756) \quad (-5.0221) \quad (-4.1933) \quad (13.3042) \quad (-8.0471) \quad (9.1790)$$

F = 33.4009 P = 0.0071

5.2.3 Random effect model

The reason why dummy variables are introduced in fixed effect model is that there is incomplete information on explanatory variables. This can also be solved by decomposing the error term to describe the missing information.

Next we adopt random effect model, which assumes that all individuals have the same intercept, and the difference between individual samples is mainly reflected in the setting of random error. However, random effect model is setup under one assumption: individual effects (random errors) are not correlated to other explanatory variables. As board meeting is not correlated to board size, board independence and board duality, we take α_i , features of each board (board meetings) as random error and detailed regression results are as follows:

$$EDA_{it} = -0.104463 - 0.000248LNCSIZE_{it} - 0.025154ROE_{it} + 0.067115LNDN_{it} - 0.012793IND_{it} + 0.024318DUA_{it}$$

$$(-7.0027) \qquad (-3.0594) \qquad (-6.8763) \qquad (15.4700) \qquad (-13.6985) \qquad (9.2690)$$

F = 86.6102 P = 0.0012

_

⁴ In panel data model, if for different cross-sections or different time series, the intercept is different, dummy variables can be introduced into the model to estimate regression parameters.

⁵ The important reason for using EVIEWS6.0 here is that it can directly show estimates of unobservable features.

5.2.4 Regression results analysis

The value of F-statistics, which suggests the overall effectiveness of model, is 33.4009 under fixed effect regression model and 86.6102 under random effect model. Meanwhile the corresponding P-values are 0.0071 and 0.0012 respectively, indicating both of the fixed effect and random effect model passed significant test, and the regression model is effective.

The regression coefficients of board size $LN(DN_{it})$ are positive, which is the opposite of predicted sign. T- statistics are 13.3042 and 15.4700 under fixed effect and random effect model respectively, both statistically significant at 5% significance level. The regression results suggest that Hypothesis1 is not supported as the larger board of directors of listed companies or the greater number of board members, the higher degree of earnings management in the company.

The regression coefficients of board independence (IND) are negative, which is consistent with the predicted sign, and both of the t-statistics passed significant test. The results indicate that the larger number of independent directors, the lower level of earnings management. This provides support for Hypothesis 2.

The regression coefficients of board duality (DUA) are positive and t-statistics passed significant test. The results show that the separation of the roles of CEO and board chair will reduce the extent of earnings management, which is consistent with Hypothesis 3.

For the control variables, the coefficients of return on equity (ROE) are negative, indicating that ROE is negatively correlated to earnings management. According to the practical situation of Chinese listed companies, ROE of most companies is ranging from little profit to 10%, so the manipulation of earnings in Chinese listed companies is relatively large. The coefficients of corporate size LnCSIZE are negative, suggesting that the larger size of Chinese listed companies, the less extent of earnings management.

5.2.5 Hausman test and conclusions

For the fixed effect and random effect model above, we will run HAUSMAN-WU test to determine which effect can better explain the regression model. The basic idea is, under the assumption that α_i is independent from other explanatory variables, the coefficients estimated from fixed effect model and random effect model are unbiased and consistent, except that fixed effect model is not effective. If the assumption does not hold, it is still consistent estimation of coefficients under fixed effect model, but not for random effect model. Therefore, under the original assumption, coefficients estimated from both models should not have significant differences. So we can conduct statistical test based on the differences of coefficients.

Table 6: Correlated Random Effects - Hausman Test

Pool: TT

Test cross-section random effects

| Test Summary | Chi-Sq. Statistic | Prob. | |
|----------------------|-------------------|-------|--------|
| Cross-section random | 2.693211 | 5 | 0.7472 |

Hausman Test in Table 7 shows that under the random effect assumption, $x^2(5)$ statistic is 2.693211 and P-Value is 0.7472, indicating that we cannot reject the random effect assumption where board feature α_i is taken as random error. Therefore, we accept random effect model. After controlling for corporate size LnCSIZE (logarithm of year-end total assets), return on equity ROE (net income/equity) and other factors, we draw the following conclusions from random effect regression model:

(1) Earnings management of Chinese listed companies is positively associated with board size.

This empirical finding indicates that a smaller board is more efficient, because communication and coordination between board members is more convenient, and a small board will react to earnings management more quickly. It provides support for Agency Theory and Organizational Behavior Theory. And our empirical result is also consistent with the empirical findings of Yermack (1996), Eisenberg et al (1998) and Wu (2000) which indentify evidence small board of directors is doing better than relatively large board of directors in monitoring managers.

(2) Earnings management of Chinese listed companies is negatively associated with board independence

This empirical result suggests that the larger number of independent directors, the lower level of earnings management. This is based on Agency Theory that the ability of the board to act as an effective monitor is dependent upon its independence from management. And our empirical finding is consistent with most of the empirical results on this field, namely, the likelihood of managers making income-increasing abnormal accruals is negatively related to the proportion of outsiders on the board.

This result also reflects the introduction of independent director system in China has made some achievements. Independent directors are playing an important role to improve the board governance of Chinese listed companies. Although there are still many areas for improvement on independent director system, the influence of independent directors is gradually increasing as independent directors begin to closely take part in firm management, monitoring and presenting a series of independent views, which helps to reduce earnings management.

(3) Earnings management of Chinese listed companies is negatively associated with the separation of the roles of CEO and board chair.

This empirical finding indicates that the separation of the roles of CEO and board chair will reduce the level of earnings management. This is based on Agency Theory that if CEO and board chair is the same person, it will be difficult to impose effective monitoring on management. And it is consistent with the empirical findings of Dechow et al (1996) and Beasley (1996) which point out if the board is controlled by general manager, earnings management is more likely to occur.

The result also provides evidence for the instruction of China Securities Regulatory Commission (CSRC), namely, separating the roles of chairman and CEO is an important method to improve corporate governance of Chinese listed companies.

6. Conclusions and Suggestions

Excessive earnings management reduces the reliability of accounting information of listed companies, thereby misleads the users in decision-making and damages the companies' reputation. Through detailed systematic research on earnings management, board governance, and the relations between board governance and earnings management of Chinese listed companies, our main findings are summarized as follows:

6.1 Earnings management of Chinese listed companies

Through reviewing theoretical and empirical research on earnings management, we adopt Modified-Jones Model to measure the extent of earnings management of Chinese listed companies. Based on the measurement results, we find that:

- (1) Earnings management in different industries: 9 industries out of 12 exaggerate the profits through upward earnings management, 3 industries hide the profits through downward earnings management. Social Services Industry shows the highest earnings management level, while Communication and Culture Industry show the lowest earnings management level.
- (2) Trend in earnings management: from 2002 to 2009, the average earnings management of Chinese listed companies gradually declined in fluctuation. The result indicates the quality of accounting information of Chinese listed companies has improved obviously in recent years.

6.2 Board governance of Chinese listed companies

Through literature review and analysis on board governance structure, we introduce four variables: board size, board independence, board duality and board meetings, to evaluate the monitoring function of the board.

The descriptive statistics of the above variables show: the average number of board members in Chinese listed companies is 10; while the average number of independent directors is 4; only less than one tenth of Chinese listed companies have board chair also serves as CEO, and this situation tends to decrease.

6.3 Empirical findings on board governance and earnings management

By using Panel Data Model, we conduct empirical research on the relations between board governance and earnings management of Chinese listed companies. After controlling for corporate size, return on equity and other factors, we get the following regression results:

- (4) Earnings management of Chinese listed companies is positively correlated to board size, that is, a smaller board is more efficient, and will impose more effective constraints on earnings management;
- (5) Earnings management of Chinese listed companies is negatively correlated with board independence, namely, the more independent directors in the board, the stronger constraints on earnings management;
- (6) Earnings management is negatively correlated to the separation of the roles of CEO and board chair, that is, the separation of the roles of CEO and board chair will reduce the level of earnings management of Chinese listed companies.

Board governance and earnings management constraint problems are of great practical and theoretical significance, hope our systematic research on this field will provide references for improving accounting information disclosure and corporate governance of Chinese listed companies. But due to the reality of China's capital market development and research capacity limitations, there are still space for further study.
