Variety of Power Sums and Divisors  
in the Moduli Space of Cubic Fourfolds

Communicated by Gavril Farkas

Abstract. We show that a cubic fourfold $F$ that is apolar to a Veronese surface has the property that its variety of power sums $VSP(F,10)$ is singular along a $K3$ surface of genus 20 which is the variety of power sums of a sextic curve. This relates constructions of Mukai and Iliev and Ranestad. We also prove that these cubics form a divisor in the moduli space of cubic fourfolds and that this divisor is not a Noether-Lefschetz divisor. We use this result to prove that there is no nontrivial Hodge correspondence between a very general cubic and its $VSP$.

1. Introduction

For a hypersurface $F \subset \mathbb{P}^n = \mathbb{P}(V^*)$ defined by a homogeneous polynomial $f \in S^dV$ of degree $d$ in $n+1$ variables, we define the variety of sums of powers as the Zariski closure

$$VSP(F,s) = \{\{[l_1], \ldots, [l_s]\} \in \text{Hilb}_s(\mathbb{P}^n) \mid \exists \lambda_i \in \mathbb{C} : f = \lambda_1 l_1^d + \ldots + \lambda_s l_s^d\},$$

in the Hilbert scheme $\text{Hilb}_s(\mathbb{P}^n)$, of the set of power sums presenting $f$ (see [20]). The minimal $s$ such that $VSP(F,s)$ is nonempty is called the rank of $F$. We will study these power sums using apolarity. Concretely, we can see the defining equation $f$ as the equation of a hyperplane $H_f$ in the dual space $S^dV^*$, and more generally, we get for each $k \leq d$ a subspace $I_f^k := [H_f : \text{Sym}^{d-k}V^*] \subset S^kV^*$.

Definition 1.1. We say that a subscheme $Z \subset \mathbb{P}^n$ is apolar to $f$ (or to $F = V(f)$) if $I_Z \subset I_f$, or, equivalently, $I_Z^d \subset I_f^d = H_f$. We use the term symmetrically, and also say that $f$ is apolar to $Z$ if $I_Z^d \subset I_f^d = H_f$.

The relation between apolarity and power sums is given by the following duality lemma (see [15]):

Lemma 1.2. Let $l_1, \ldots, l_s \in V$ be linear forms. Then $f = \lambda_1 l_1^d + \ldots + \lambda_s l_s^d$ for some $\lambda_i \in \mathbb{C}^*$ if and only if $Z = \{[l_1], \ldots, [l_s]\} \subset \mathbb{P}(V)$ is apolar to $F = V(f)$.

In the case $F \subset \mathbb{P}^5$ is a general cubic hypersurface, the rank of $F$ is 10 and the variety of 10-power sums of $F$ is 4-dimensional. In the paper [15], Iliev and the first author exhibited cubic fourfolds $F_{IR}(S)$ associated to $K3$ surfaces $S$ of degree 14 obtained as the transverse intersection $G(2, 6) \cap P_S$ of the Grassmannian $G(2, 6)$ with a codimension 6 linear space $P_S$ of $P(\Lambda^2 V_6) = P^{14}$ (see Section 2 for the precise construction). On the other hand Beauville and Donagi, in [3], associate to such a $K3$ surface $S$ the Pfaffian cubic $F_{BD}(S)$ which is the intersection of the Pfaffian cubic in $P(\Lambda^2 V_6)$ with the $P^5 \subset P(\Lambda^2 V_6^*)$ orthogonal to $P_S$. The following result is proved in [15].

Theorem 1.3. For general $S$ as above, the variety $VSP(F_{IR}(S), 10)$ is isomorphic to the family of secant lines to $S$, i.e. to $Hilb_2(S)$.

Combining this result with those of Beauville and Donagi [3], we conclude that $VSP(F_{IR}(S), 10)$ is isomorphic to the Fano variety of lines in the Pfaffian cubic fourfold $F_{BD}(S)$. Theorem 1.3 also says that $VSP(F_{IR}(S), 10)$ is a smooth hyperkähler fourfold. A deformation argument ([15, proof of Theorem 3.17]), may therefore be applied to prove

Corollary 1.4. For a general cubic fourfold $F$, the variety $VSP(F, 10)$ is a smooth and irreducible hyperkähler fourfold.

Remark 1.5. Note that the statement of [15, Theorem 3.17] is incorrect, and was corrected in [16].

Recall from [3] that the Hodge structure on $H^4(F, \mathbb{Q})$, for $F$ a smooth cubic fourfold, is up to a shift isomorphic to the Hodge structure on $H^2$ of its variety of lines, the isomorphism being induced by the incidence correspondence. The construction of Iliev and Ranestad provides for general $F$ a second hyperkähler fourfold $VSP(F, 10)$ associated to $F$. A natural question is whether there is also an isomorphism of Hodge structures of bidegree $(-1, -1)$ between $H^4(F, \mathbb{Q})$ and $H^2(VSP(F, 10), \mathbb{Q})$. Note that Theorem 1.3 above combined with the results of Beauville and Donagi does not imply this statement even for the particular cubic fourfolds of the type $F_{IR}(S)$, because the Hodge structures on degree 4 cohomology of the cubes $F_{IR}(S)$ and $F_{BD}(S)$ could be unrelated.

Another way of stating our question is whether the two hyperkähler fourfolds associated to $F$, namely its variety of lines and $VSP(F, 10)$, are “isogenous” in the Hodge theoretic sense.

We prove in this paper that such a Hodge correspondence does not exist for general $F$. 
Theorem 1.6. For a very general cubic fourfold \( F \), there is no nontrivial morphism of Hodge structures

\[ \alpha : H^4(F, \mathbb{Q})_{prim} \to H^2(VSP(F, 10), \mathbb{Q}). \]

In particular, there is no correspondence \( \Gamma \in CH^3(F \times VSP(F, 10)) \), such that

\[ \left[ \Gamma \right]_* : H^4(F, \mathbb{Q})_{prim} \to H^2(VSP(F, 10), \mathbb{Q}) \]

is non zero.

This theorem cannot be proved locally (in the usual topology), because the two variations of Hodge structures have the same shape and we have no description of the periods of \( VSP(F, 10) \): it is even not clear how its holomorphic 2-form is constructed. In fact, by the general theory of the period map, there exists locally near a general point of the moduli space of cubic fourfolds and up to a local change of holomorphic coordinates, an isomorphism between the complex variations of Hodge structure on \( H^4(F, \mathbb{C})_{prim} \) and \( H^2(VSP(F, 10), \mathbb{C})_{prim} \).

Indeed, by the work of Beauville and Donagi, we know that the variation of Hodge structure on \( H^4(F, \mathbb{C})_{prim} \) is isomorphic (with a shift of degree) to the variation of Hodge structure on \( H^2_{prim} \) of the corresponding family of varieties of lines, hence in particular this is (up to a shift of degree) a complete variation of polarized Hodge structures of weight 2 with Hodge numbers \( h^{2,0} = 1, h^{1,1}_{prim} = 20 \). The same is true for the variation of Hodge structure on \( H^2(VSP(F, 10), \mathbb{C})_{prim} \) once one knows that the family of \( VSP \)'s is locally universal at the general point, which is equivalent to saying that the deformations of \( VSP(F, 10) \) induced by the deformations of \( F \) have 20 parameters, this last fact being easy to prove. Hence both complex variations of Hodge structures are given (locally near a general point in the usual topology) by an open holomorphic embedding into a quadric in \( \mathbb{P}^{21} \), and thus they are locally isomorphic since a quadric is a homogeneous space.

Notice that if we consider plane sextic curves instead of cubic fourfolds, then we are faced with an analogous situation, namely we can associate naturally to a plane sextic curve \( C \) two \( K3 \) surfaces, the first one being the double cover of \( \mathbb{P}^2 \) ramified along \( C \), and the other one being the variety of power sums \( VSP(C, 10) \), which has been proved by Mukai [19] to be a smooth \( K3 \) surface for general \( C \) (see also [10]).

Theorem 1.6 will be obtained as a consequence of the following construction which relates the Mukai construction for plane sextic curves to the Iliev-Ranestad construction for cubic fourfolds. This involves the introduction of the closed algebraic subset of the moduli space of the cubic \( F \) parameterizing cubic fourfolds apolar to a Veronese surface. This subset, which we will prove to be a divisor \( D_{V-ap} \), will now be introduced in more detail.

Let \( W \) be a 3-dimensional vector space, and \( V := S^2W \), which is a 6-dimensional vector space. There is a natural map

\[ s : S^6W \to S^3V \]

which is dual to the multiplication map

\[ m : S^3(S^2W^*) \to S^6W^*. \]
If $a \in W$, we have

\[(2)\]  
$s(a^6) = (a^2)^3$.

The map $s$ associates to a plane sextic curve $C$ with equation $g \in S^6W$ a four dimensional cubic $F$ with equation $f = s(g) \in S^3V$. Note that we recover $g$ from $f$ using the multiplication morphism $m': S^3V \to S^6W$. Indeed we have

\[(3)\]  
$m'(f) = g$,

as an immediate consequence of $(2)$.

**Lemma 1.7.** The cubic polynomials in the image of $s$ are exactly those which are apolar to the Veronese surface $\Sigma \subset P(S^2W)$.

**Proof.** Indeed, by definition of apolarity, a cubic hypersurface defined by an equation $f \in S^3V$ is apolar to the Veronese surface if and only if the hyperplane $H_f \subset S^3V^*$ determined by $f$ contains the ideal $I_\Sigma(3)$. Equivalently, $(f,k) = 0$, for $k \in I_\Sigma(3)$. But as we have $f = s(g)$, $(3)$ tells that

$$(f,k) = (g,m(k)).$$

By definition of the Veronese embedding, the map

$$m : S^3V^* \to S^6W^*$$

is nothing but the restriction map to $\Sigma$, so that $m(k) = 0$ and $(f,k) = 0$ for $k \in I_\Sigma(3)$. For the converse, note that the map $s$ is injective and that $\dim_C S^6W = \dim_C S^3V^* - \dim_C I_\Sigma(3)$, so if $(f,k) = 0$ for every $k \in I_\Sigma(3)$, then $f$ is in the image of $s$. \qed

It follows that the $K3$ surface $VSP(C,10)$ embeds naturally in $VSP(F,10)$ and we will prove in Section 5:

**Theorem 1.8.** The variety $VSP(F,10)$ is singular along $VSP(C,10)$. For a general choice of $C$, the variety $VSP(F,10)$ is smooth away from the $K3$ surface $VSP(C,10)$ and has nondegenerate quadratic singularities along $VSP(C,10)$.

Our strategy for the proof of Theorem 1.6 is the following. We will first prove that $D_{V-ap}$ is a divisor, and that the divisor $D_{V-ap}$ is not a Noether-Lefschetz divisor in the moduli space $\mathcal{M}$ of cubic fourfolds (Proposition 4.16), which means that for a general cubic parameterized by this divisor, there is no nonzero Hodge class in $H^4(F,\mathbb{Q})_{prim}$. Secondly, using Theorem 1.8, we will prove that $D_{V-ap}$ is a Noether-Lefschetz divisor for the family $VSP(F,10)$ of varieties of power sums parameterized by a Zariski open set of $\mathcal{M}$, which has to be interpreted in the sense that the generic Picard rank of the extension along $D_{V-ap}$ of the variation of Hodge structure on the degree 2 cohomology of $VSP(F,10)$ is at least 2.

Both proofs involve a careful analysis of the variety of power sums $VSP(F,10)$ with results that we believe may have independent interest. Indeed, the set theoretic definition given in (1) of $VSP(F,s)$ as a closure in the Hilbert scheme does not give a priori any information on its schematic structure. We obtain in Section 3 the following results in the case of $VSP(F,10)$ for cubic fourfolds.
Let $U \subset \text{Hilb}_{10}(\mathbb{P}^5)$ be the open set of zero-dimensional subschemes imposing independent conditions to cubics. There is vector bundle $E$ of rank 46 on $U$, with fiber $I_Z(3)$ over the point $[Z] \in \text{Hilb}_{10}(\mathbb{P}^5)$.

**Theorem 1.9.** (i) (cf. Proposition 3.1) For a general choice of $F$ in the complement of explicit divisors in the moduli space of cubic fourfolds, the variety of power sums $VSP(F,10)$ is contained in $U$ and is the zero locus of a section of the vector bundle $E^*$ on $U$.

(ii) (cf. Proposition 3.5) For a general cubic fourfold $F$, the variety $VSP(F,10)$ does not intersect the singular locus of $\text{Hilb}_{10}(\mathbb{P}^5)$.

(iii) (cf. Proposition 4.11 and Corollary 4.12) These results remain true for a general cubic fourfold apolar to a Veronese surface.

In order to prove these results, we were led to introduce new divisors in the moduli space of cubic fourfolds, that is divisors in $\mathbb{P}(S^3V)$ invariant under the action of $\text{PGL}(6)$, along which properties stated above fail. Many $\text{PGL}(6)$-invariant divisors were already known: the discriminant hypersurface parameterizing singular cubic fourfolds and the infinite sequence of divisors of smooth cubic fourfolds containing a smooth surface which is not homologous to a complete intersection, introduced by Brendan Hassett [14]. The latter sequence includes the Beauville-Donagi hypersurface parameterizing Pfaffian cubics. These are all Noether-Lefschetz divisors. Concerning the new divisors $D_{rk3}$, $D_{copl}$ and $D_{V-ap}$ we introduce in this paper (see Section 2), we prove that $D_{V-ap}$ is not a Noether-Lefschetz divisor, and it is presumably the case that neither $D_{rk3}$ nor $D_{copl}$ are Noether-Lefschetz divisors. We do not know whether the Iliev-Ranestad divisor $D_{IR}$ parameterizing the Iliev-Ranestad cubics is a Noether-Lefschetz divisor. As a consequence of Theorem 1.3, the Picard rank of the variety $VSP(F,10)$ jumps to 2 along this divisor. Therefore proving that $D_{IR}$ is not a Noether-Lefschetz divisor could have been another approach to Theorem 1.6.

**Acknowledgments.** We would like to thank an anonymous referee for numerous suggestions that improved the presentation of our proofs.

1.1. **Notation.** We give the numerical information of the minimal free resolution of a graded $S = \mathbb{C}[x_0, \ldots, x_r]$-module

$$0 \leftarrow M \leftarrow F_0 \leftarrow F_1 \leftarrow \ldots \leftarrow F_n \leftarrow 0$$

with $F_i = \bigoplus_{j \in \mathbb{Z}} \beta_{ij} (-j)$ in Macaulay2 notation [18], i.e. in the form

$$\begin{array}{ccccccc}
\beta_{00} & \beta_{11} & \beta_{22} & \ldots & \beta_{n,n} \\
\beta_{01} & \beta_{12} & \beta_{23} & \ldots & \beta_{n,n+1} \\
\vdots & \vdots & \vdots & \ldots & \vdots \\
\beta_{0m} & \beta_{1,m+1} & \beta_{2,m+2} & \ldots & \beta_{n,n+m}
\end{array}$$

The $\beta_{ij}$ counts the number of linearly independent generators of $M$ of degree $j+1$, while the $\beta_{ij}$, for $i > 0$ counts the homogeneous sets of linearly independent syzygies of order $i$.
2. Some divisors in the moduli space of cubic fourfolds

Let \( V = \mathbb{C}^6 \). We introduce in this section two \( \text{PGL}(V) \)-invariant divisors \( D_{rk3} \) and \( D_{copl} \) in the open set \( \text{P}(S^3V)_{\text{reg}} \) of the projective space \( \text{P}(S^3V) \) parameterizing smooth cubic fourfolds. We also recall the definition of the Iliev-Ranestad divisor \( D_{IR} \). These divisors are crucial in the proof that the set \( D_{V-ap} \) considered in the introduction is also a divisor (Corollary 4.10 in Section 4).

The divisor \( D_{rk3} \). This is the set of cubic forms \([f] \in \text{P}(S^3V)_{\text{reg}} \) such that \( f \) has a partial derivative of rank \( \leq 3 \).

**Lemma 2.1.** The set of cubic forms \([f] \in \text{P}(S^3V)_{\text{reg}} \) such that \( f \) has a partial derivative of rank \( \leq 3 \) is an irreducible divisor in \( \text{P}(S^3V)_{\text{reg}} \).

**Proof.** If \([f] \in D_{rk3} \), there exist a point \( p \in \text{P}(V^*) \) and a plane \( P(W) \subset \text{P}(V^*) \) such that

\[
\frac{\partial^2 f}{\partial p \partial w} = 0, \forall w \in W. \tag{4}
\]

Consider the case where \( p \) does not belong to \( P(W) \) and let us compute how many conditions on \( f \) are imposed by (4) for fixed \( p, W \). We may choose coordinates \( X_i, i = 0, \ldots, 5 \), such that \( W \) is defined by \( X_i = 0, i = 3, 4, 5 \) and \( p \) is defined by equations \( X_i = 0, i = 0, \ldots, 4 \). Then \( f \) has to satisfy the conditions

\[
\frac{\partial^2 f}{\partial X_5 \partial X_i} = 0, \text{ for any } i \in \{0, 1, 2\}. \tag{5}
\]

Equivalently, we have

\[
\frac{\partial^3 f}{\partial X_5 \partial X_i \partial X_j} = 0, \text{ for any } i \in \{0, 1, 2\} \text{ and any } j \in \{0, \ldots, 5\}.
\]

The number of coefficients of \( f \) annihilated by these conditions is 15. As the pair \((p, W)\) has 14 parameters, we conclude that the \( f \) satisfying these equations for some \((p, W)\) fill-out at most a hypersurface. On the other hand, the map

\[
\text{P}(S^3V)_{\text{reg}} \to G(6, S^2V); [f] \mapsto \left( \frac{\partial f}{\partial X_0}, \ldots, \frac{\partial f}{\partial X_5} \right)
\]

is generically injective; for general \( f \), the apolar ideal is generated by the quadrics orthogonal to the partials of \( f \), and according to Macaulay's theorem, the apolar ideal defines \( f \) up to scalar. The rank 3 locus in \( \text{P}(S^2V) \) has codimension 6, so the 6-dimensional subspaces of \( S^2V \) that intersect the rank 3 locus form a hypersurface section in \( G(6, S^2V) \). Therefore the cubic forms that have a partial of rank 3 form at least a divisor in \( \text{P}(S^3V)_{\text{reg}} \), i.e. they form exactly a divisor. It is irreducible, because it is dominated by a projective bundle over the parameter space for \((p, W)\). Denote this hypersurface by \( D_{rk3} \).

To complete the argument we consider the degenerate situation where \( p \in \text{P}(W) \). It may be seen as a limit of the above case: We may choose coordinates \( X_i, i = 0, \ldots, 5 \), such that \( W \) is defined by \( X_i = 0, i = 3, 4, 5 \) and \( p_t \) is defined...
by equations $X_i = 0, i = 1, \ldots, 4$ and $X_5 = tX_0$. Thus $p_0 \in \mathbb{P}(W)$. For any $t$, we consider the cubic forms $f$ that satisfy the conditions
\[
\frac{\partial^2 f}{\partial X_0 \partial X_i} - t \frac{\partial^2 f}{\partial X_5 \partial X_i} = 0, \quad i = 0, 1, 2.
\]
Equivalently, we have
\[
(6) \quad \frac{\partial^3 f}{\partial X_0 \partial X_i \partial X_j} - t \frac{\partial^3 f}{\partial X_5 \partial X_i \partial X_j} = 0, \quad i = 0, 1, 2 \forall j.
\]
These are 15 linearly independent conditions on the coefficients of $f$ for any value of $t$. In particular, any cubic form $f_0$ satisfying the conditions with $t = 0$ is a limit of forms $f$ that satisfy the conditions for $t \neq 0$ as $t$ tends to 0. So also in the degenerate situation, the forms lie in the irreducible hypersurface $D_{rk3}$.

Note the following other characterization of $D_{rk3}$:

**Lemma 2.2.** A cubic form belongs to $D_{rk3}$ if it has a net (a 3-dimensional vector space) of partial derivatives which are all singular in a given point $p$.

**Proof.** The fact that $f$ has a net of partial derivatives which are singular in a point $p$ is equivalent to the vanishing $\partial_p(\partial w_i f) = 0$ for three independent vectors $w_i$. This holds if and only if $\partial w_i(\partial_p f) = 0$ for $i = 1, 2, 3$, which in turn is equivalent to the fact that the partial derivative $\partial_p f$ has rank $\leq 3$. □

**The divisor $D_{copl}$.** The subset $D_{copl} \subset \mathbb{P}(S^3V)_{reg}$ is the Zariski closure of the set of forms $f$ which can be written as
\[
(7) \quad f = \sum_{i=1}^{10} a_i^3,
\]
such that four of the linear forms $a_i \in V$ are coplanar.

**Lemma 2.3.** $D_{copl}$ is an irreducible divisor in $\mathbb{P}(S^3V)_{reg}$.

**Proof.** The set $D_{copl}$ is irreducible, since it is dominated by the irreducible algebraic set parameterizing the 10 linear forms, four of which are coplanar. If we count dimensions, we find that this last algebraic set has dimension 56. However, we observe that a general cubic form $g$ in 3 variables has a two-dimensional variety of power sums $VSP(E, 4)$, where $E = V(g)$. If $f = \sum_{i=1}^{10} a_i^3$, where $a_1, \ldots, a_4$ are coplanar, we have
\[
(8) \quad f = g(b_1, b_2, b_3) + \sum_{i=5}^{10} a_i^3,
\]
where the $a_i$’s for $i \leq 4$ are linear combinations of the $b_i$’s. As there is a 2-parameter family of ways of writing $g$ as a sum of four powers of linear forms in the $b_i$’s, we conclude that there is a 2-parameter family of ways of writing $f$ as in (7). This proves that $D_{copl}$ has codimension at least 1. To show that
it actually is a divisor, we exhibit an affine subfamily of $D_{\text{coul}}$ of codimension one in the space of cubic forms. In fact if we let
\[ b_1 = x_0 + b'_0, \quad b_2 = x_1 + b'_2, \quad b_3 = x_2 + b'_3 \]
and
\[
\begin{align*}
  a_5 &= x_0 - x_1 + x_3 + x_4 + a'_5, \\
  a_6 &= x_1 + x_2 - x_3 - x_4 - x_5 + a'_6, \\
  a_7 &= x_2 + x_3 - x_4 + x_5 + a'_7, \\
  a_8 &= x_3 + a'_8, \\
  a_9 &= x_4 + a'_9, \\
  a_{10} &= x_5 + a'_{10},
\end{align*}
\]
with $b'_1, b'_3, a'_5, ..., a'_{10} \subset V$, then
\[
f = g(b_1, b_2, b_3) + \sum_{i=5}^{10} a_i^3
\]
belongs to $D_{\text{coul}}$ for every 9-tuple of linear forms $b'_1, ..., b'_3, a'_5, ..., a'_{10}$. The summands in $f$ that are linear in the $b'_i$ and $a'_i$ span the tangent space to this family at the origin, where $b'_1 = ... = a'_{10} = 0$. This space may thus be shown, with Macaulay2 [18], to have dimension 54. Therefore the family is a divisor. □

The divisor $D_{\text{IR}}$. This is the divisor constructed by Iliev and Ranestad in [15]. It parameterizes the cubic fourfolds $F_{\text{IR}}(S)$ mentioned in the introduction, associated to K3 surfaces $S$ which are complete intersections of the Grassmannian $G(2,6) \subset \mathbb{P}^{14}$ with a $\mathbb{P}^5_S$. More precisely, these cubic fourfolds are defined as follows: Dual to $\mathbb{P}^5_S$, we get a $\mathbb{P}^5_S \subset \mathbb{P}^{14}$. The dual projective space $\mathbb{P}^{14}$ contains the Grassmannian of lines $G(2,6)$ and for generic choice of $\mathbb{P}^5_S$, the intersection $\mathbb{P}^5_S \cap G(2,6)$ is empty. It is then proved in [15] that the ideal of cubic forms on $\mathbb{P}^{14}$ vanishing on $G(2,6)$ restricts to a hyperplane in $H^0(\mathbb{P}^5_S, \mathcal{O}_{\mathbb{P}^5_S}(3))$. This hyperplane in turn determines a cubic fourfold in $\mathbb{P}^5_S$.

For later use in the paper, we recall and extend a characterization from [15] of apolar length 10 subschemes to cubic forms $[f] \in D_{\text{IR}}$ in terms of quartic surface scrolls, i.e. rational normal surface scrolls in $\mathbb{P}^5$.

**Lemma 2.4.** Let $f$ be a cubic form of rank 10, such that $[f] \in D_{\text{IR}}$. Then the general subscheme of length 10 apolar to $f$ is the intersection of two quartic surface scrolls. In particular $f$ is apolar to a quartic surface scroll.

Conversely, if $f$ is a cubic form of rank 10 apolar to a quartic surface scroll, then $[f] \in D_{\text{IR}}$.

**Proof.** The first part is shown in [15]: Let $S = G(2,6) \cap \mathbb{P}^5_S$ be the K3-surface section associated to $F = V(f)$, i.e. $F = F_{\text{IR}}(S)$ in the notation of loc. cit. Then $S$ parameterizes quartic surface scrolls apolar to $f$, and the two scrolls corresponding to a pair of points on $S$ intersect in a length 10 subscheme apolar to $f$ (Lemma 2.9 and the proof of Theorem 3.7 loc.cit.).

For the second part, if $f$ is apolar to a quartic surface scroll, then by dimension count, $f$ has a 2-dimensional family of length 10 apolar subschemes on this scroll. The general such subscheme $Z$ has a Gale transform in $\mathbb{P}^4$ contained in a smooth quadric surface [11, Corollary 3.3]. Furthermore, the two rulings in the quadric surface correspond to two quartic surface scrolls that contain $Z$, see
Variety of Power Sums and Divisors . . .

[11, Example 3.4], where an analogous case is explained. Therefore $f$ is apolar to a 2-dimensional family of quartic surface scrolls. Now, the family of quartic surface scrolls in $\mathbb{P}^5$ is irreducible of dimension 29, and each scroll is apolar to a 27-dimensional space of cubic forms, so there is an irreducible 54-dimensional family of cubic forms apolar to some quartic surface scroll. This family must coincide with the divisor $D_{1fr}$ since it contains it.

□

3. Apolarity and syzygies

In this section we first show that for a general cubic fourfold $F \subset \mathbb{P}(V^*)$, the variety $VSP(F,10)$ is defined as the zero locus, inside the Hilbert scheme, of a section of a vector bundle. In fact the variety $VSP(F,10)$ is then entirely contained in the set $U \subset \text{Hilb}_{10}(\mathbb{P}(V))$ of zero-dimensional subschemes imposing independent conditions on cubics (Proposition 3.1), and $Z$ is apolar to $F$ for every $[Z] \in VSP(F,10)$. Furthermore, after defining the cactus rank of a cubic fourfold $F$ (Definition 3.2), we note that any scheme of minimal length apolar to $F$, is locally Gorenstein, and show, as a consequence, that $VSP(F,10)$ does not meet the singular locus of $\text{Hilb}_{10}(\mathbb{P}(V))$ for a general $F$ (Proposition 3.5).

We also show that if $F$ is general, then the cactus rank coincides with the rank and $VSP(F,10)$ contains all schemes of length 10 that are apolar to $F$ (Corollary 3.6).

In the second part of this section we give a criterion (Lemma 3.18) for a cubic form $f$ to have cactus rank 10 in terms of a syzygy variety of its apolar ideal $I_f$. When a cubic fourfold $F \subset \mathbb{P}(V^*)$ has cactus rank 10, then the union of the apolar subschemes of length 10 forms a hypersurface $V_{10}(F)$ in $\mathbb{P}(V)$. We will show (Lemma 3.21) that $V_{10}(F)$ is a syzygy variety of $I_f$, and analyze its singular locus.

At the end of this section we show (Proposition 3.5) that $VSP(F,10)$ does not meet the singular locus of $\text{Hilb}_{10}(\mathbb{P}(V))$ for a general $F$. The results of this section that are used later, are formulated in two lemmas and two propositions. Lemmas 3.18 and 3.21 will be used in Section 4 to prove that a general $[f] \in D_{V-ap}$ is apolar to finitely many Veronese surfaces, from which we will deduce that $D_{V-ap}$ is a divisor. Propositions 3.1 and 3.5 are applied in Section 4 to show that for a general $[f] \in D_{V-ap}$, the length 10 subscheme $Z$ is apolar to $f$ for every $[Z] \in VSP(F,10)$ and is a smooth point in $\text{Hilb}_{10}(\mathbb{P}(V))$.

3.1. Apolar subschemes of length 10.

**Proposition 3.1.** Let $F \subset \mathbb{P}(V^*)$ be a cubic fourfold defined by a general form $f \in \text{Sym}^3V$. Then any length 10 subscheme $[Z] \in VSP(F,10)$ imposes independent conditions to cubics, i.e. $h^1(I_Z(3)) = 0$, and is apolar to $f$, that is $I_Z(3) \subset H_f$.

Furthermore, if there is a codimension 1 component of the set of smooth cubic fourfolds not satisfying this conclusion, it must be one of the two divisors $D_{rk3}$ and $D_{cop}$ introduced in the previous section.

Documenta Mathematica 22 (2017) 443–492
Note that the second statement follows from the first using Lemma 1.2 and the fact that the condition \( I_Z(3) \subseteq H_f \) is a closed condition on the open set \( U \subseteq \text{Hilb}_{10}(P(V)) \) of zero-dimensional subschemes imposing independent conditions to cubics.

The proof of Proposition 3.1 is postponed until later in this section. The proposition will be crucial in the study of the schematic structure of \( VSP(F,10) \), for \( f \) satisfying the above conditions. To see this, we first consider finite subschemes of minimal length apolar to \( f \). A form \( f \) of rank 10 may be apolar to subschemes of length less than 10. This motivates the notion of cactus rank of \( f \):

**Definition 3.2.** The cactus rank of a form \( f \) or equivalently of the hypersurface \( F = V(f) \subseteq P^n \) is the minimal length of a 0-dimensional subscheme \( Z \) of \( \mathbf{P}^n \) which is apolar to \( f \) (resp. \( F \)).

**Remark 3.3.**

1. Buczyński and Buczyński showed in [4, Proposition 2.2, Lemma 2.3] that a finite subscheme \( Z \), that is apolar to \( f \) and has length equal to its cactus rank, is locally Gorenstein.

2. Casnati, Jelisiejew and Notari have shown that any local Gorenstein scheme of length at most 13 is smoothable (cf. [8, Theorem A]).

Since the smooth apolar schemes form an open set in its component of the Hilbert scheme, we get:

**Lemma 3.4.** If \( F \) is a general cubic fourfold of rank 10, then the cactus rank of \( F \) is also 10.

*Proof.* Since Gorenstein schemes of length \( \leq 9 \) are smoothable, cubic forms \( f \) of cactus rank \( \leq 9 \) lie in the closure of forms of rank \( \leq 9 \). But the closure of the set of forms of rank \( \leq 9 \) is a proper subset of the set of cubic forms, so the general form of rank 10 must also have cactus rank 10. \( \square \)

The Proposition 3.1 provides a criterion for \( VSP(F,10) \) to avoid the singular locus of \( \text{Hilb}_{10}(P(V)) \).

**Proposition 3.5.** Let \( V = \mathbf{C}^g \), and let \( F \) be a fourfold defined by a cubic form \( f \in \text{Sym}^3 V \) with no partial derivative of rank \( \leq 3 \). If \( f \) has cactus rank 10 and \( Z \) is apolar to \( f \) for every \([Z] \in VSP(F,10)\), then \( VSP(F,10) \) does not intersect the singular locus of \( \text{Hilb}_{10}(P(V)) \).

*Proof.* Let \([Z] \in VSP(F,10)\), then, by Remark 3.3, the scheme \( Z \) is locally Gorenstein. Consider the morphism \( q_f : P(V) \to P(Q_f^*) \) defined by the space of quadrics \( Q_f \) that are apolar to \( F \). Then the linear span of the image \( q_f(Z) \) has, by Lemma 3.9, dimension 2 or 3. Since \( f \) has no partial of rank \( \leq 3 \), the morphism \( q_f \) is, by Lemma 3.8, an embedding, so the scheme \( Z \) is embeddable in \( P^3 \). By [17] and [9, Corollary 2.6], the corresponding point \([Z]\) is smooth in the Hilbert scheme. \( \square \)
By Remark 3.3, the open set \( U_G \subset U \subset \text{Hilb}_{10}(\mathbb{P}^5) \) of length 10 locally Gorenstein subschemes that impose independent conditions to cubics is contained in the irreducible component of the smooth subschemes.

**Corollary 3.6.** Let \( F = V(f) \) be a general cubic fourfold. Then \( \text{VSP}(F, 10) \) is the zero locus of a section \( \sigma_f \) of the vector bundle \( E \) on \( U_G \) of rank 46 with fiber \( I_Z(3)^* \). In particular, \( \text{VSP}(F, 10) \) admits a natural smooth and connected scheme structure and contains all subschemes of length 10 that are apolar to \( F \).

**Proof.** Indeed, let \( \sigma_f \) be the section of \( E \) given by \( Z \mapsto f|_{I_Z(3)}^* \), where \( f^* \) denotes the linear form on \( \text{Sym}^3 V^* \) corresponding to \( f \). Then \( \sigma_f \) vanishes on \( \text{VSP}(F, 10) \) by Proposition 3.1. The set \( U_G \) is irreducible and the set of sections \( \sigma_f \) clearly has no basepoints. By Proposition 3.5, the general section vanishes only in the smooth locus of \( U_G \), so the zero locus of \( \sigma_f \) is smooth and connected for general \( F \).

The proof of Proposition 3.1 will need a few preparatory lemmas. For a cubic form \( f \in S^3 V \) such that \( F = V(f) \) is not a cone, let \( P(f) \subset \mathbb{P}(S^2 V) \) be the space of partial derivatives of \( f \) and \( Q_f = P(f)^\perp \subset S^2 V^* \). Then \( P(f) \) is 6-dimensional and hence \( \dim Q_f = 15 \). Note that \( Q_f = [H_f : V^*] \), where \( H_f \subset S^3 V^* \) is the hyperplane defined by \( f^* \); indeed we may identify the space of partials \( P(f) \) with the image \( V^*(f) \subset S^2 V \), so if \( q \in S^2 V^* \), then \( q \cdot V^*(f) = 0 \) if and only if \( q(P(f)) = 0 \).

Consider now a subscheme \( Z \subset \mathbb{P}^5 \) of length 10. Since \( Z \) imposes at most 10 conditions on quadrics, the space \( I_Z(2) \) of quadrics in the ideal has dimension at least 11, with equality for an open set of schemes \( Z \). Likewise, the ideal is generated in degree 2, for an open set of length 10 schemes \( Z \): If \( Z \) is the intersection of a rational normal quintic curve and a quadric, then \( I_Z(2) \) has dimension 11 and generate the ideal \( I_Z \). Therefore this is the case also for a general \( Z \).

Thus, in particular, if \( F \) is a general cubic fourfold and \( [Z] \in \text{VSP}(F, 10) \) is general, then \( I_Z(2) \) has dimension 11 and generate the ideal \( I_Z \). Furthermore, by Lemma 1.2, \( I_Z(2) \subset Q_f \). It follows that the rank of the evaluation map

\[
Q_f \to H^0(O_Z(2))
\]

is at most 4 for a general \( [Z] \in \text{VSP}(F, 10) \), and by semicontinuity of the rank, the same remains true for any \( [Z] \in \text{VSP}(F, 10) \). Therefore

**Lemma 3.7.** Let \( f \in S^3 V \) be a cubic form such that \( F = V(f) \) is not a cone, and let \( [Z] \in \text{VSP}(F, 10) \), then \( \dim I_Z(2) \cap Q_f \geq 11 \).

The linear system of quadrics \( Q_f \) gives a rational map

\[
q_f : \mathbb{P}(V) \dashrightarrow \mathbb{P}(Q_f^*),
\]

defined as the composition of the Veronese map \( \mathbb{P}(V) \to \mathbb{P}(S^2 V) \) and the projection from the subspace \( P(f) \subset \mathbb{P}(S^2 V) \).

The following lemma is an immediate consequence of this description.
LEMMA 3.8.

1. $q_f$ is a morphism if and only if $f$ has no partials of rank $\leq 1$.
2. $q_f$ is an embedding if and only if $f$ has no partials of rank $\leq 2$.
3. $q_f$ is an embedding and the image $X_f := q_f(P(V))$ contains no subscheme of length 3 contained in a line if and only if $f$ has no partial derivative of rank $\leq 3$, i.e. $f \notin D_{r \leq 3}$.

This lemma allows us to find possible schemes $Z$ such that $\dim I_Z(2) \cap Q_f \geq 11$.

LEMMA 3.9. Let $f$ be a cubic form with no partial derivative of rank $\leq 3$, let $X_f = q_f(P(V))$, as above, and let $P \subset P(Q_f^3)$ be a $P^3$.

If $X_P := P \cap X_f$ contains a curve, then $X_P$ is the image by $q_f$ of a line and a residual finite subscheme.

In particular, if $F = V(f)$, $[Z] \in VSP(F, 10)$ and $Z_f = q_f(Z)$, then the linear span of $Z_f$ is a $P^2$ or a $P^3$, and if $I_Z(2) \cap Q_f$ is contained in the ideal of a curve, this curve is a line.

Proof. Indeed, by Lemma 3.8 (3), $q_f$ is an embedding and the image $X_f$ has no trisecant line. Since it is a linear projection of the second Veronese embedding, every curve in the image has even degree. Consider now a 3-space $P \subset P^3$ and the intersection $X_P = P \cap X_f$. Since every surface in $P$ contains a line or has a trisecant line, $X_P$ cannot contain a surface. Furthermore, the only curves in $P$ of even degree with no trisecant lines are the conics and the complete intersections of two quadric surfaces (e.g. [2]). But a complete intersection of two quadric surfaces is not the second Veronese embedding of a curve. Therefore, if $X_P$ contains a curve, $X_P$ is the union of a conic and a residual finite subscheme.

If $[Z] \in VSP(F, 10)$, then $\dim I_Z(2) \cap Q_f \geq 11$ by Lemma 3.7, so the span $\langle Z_f \rangle$ is at most a $P^3$. On the other hand, $Z_f$ must span at least a plane, since $X_f$ has no trisecant line, so that $3 \geq \dim \langle Z_f \rangle \geq 2$. The linear span $\langle Z_f \rangle$ intersects $X_f$ in the zero locus of $I_Z(2) \cap Q_f$, so the last claim in the lemma now follows from the first.

Notice that the span $\langle Z_f \rangle$, whether $Z$ is apolar to $f$ or not, has dimension 2 (resp. 3) if and only if $I_Z(2) \cap Q_f$ has dimension 12 (resp. 11).

LEMMA 3.10. Let $V = \mathbb{C}^9$, and let $f \in \text{Sym}^3 V$ be a cubic form with no partial derivative of rank $\leq 3$. Let $Z \subset P(V)$ be a subscheme of length 10, and assume that $I_Z(3)$ has codimension at most 9 in $\text{Sym}^3 V^*$. Let $\Gamma \subset P(V)$ be the zero locus of the space of quadrics $I_Z(2) \cap Q_f$.

1. If $\dim I_Z(2) \cap Q_f = 12$, then $\Gamma$ is a line.
2. If $\dim I_Z(2) \cap Q_f = 11$, then $\Gamma$ is the union of a line and a residual finite subscheme.

Proof. Let $Z \subset P(V)$ be a subscheme of length 10 and assume that $I_Z(3)$ has codimension at most 9 in $\text{Sym}^3 V^*$. Notice first that $\dim I_Z(2) \geq 12$. In fact, the subscheme $Z$ does not impose independent conditions on cubics, i.e.
Let $\Gamma$ be a general hyperplane that contains $Z$. If $\Gamma$ contains at least a subscheme of length 5 in a plane, we may argue as for $Z_0$. The residual scheme $Z_1 = Z \setminus Z_0$ therefore has length at least 2 and at most 6. Let $H = \{ h = 0 \}$ be a general hyperplane that contains $Z_0$. Then multiplication by $h$ defines a sequence of sheaves of ideals

$$0 \to \mathcal{I}_Z(2) \to \mathcal{I}_Z(3) \to \mathcal{O}_H(3) \to 0,$$

which is exact. Since $h^1(\mathcal{O}_H(3)) = 0$, $h^1(\mathcal{I}_Z(3)) > 0$ implies that

$$h^1(\mathcal{I}_Z(2)) > 0,$$

and hence that $\dim \mathcal{I}_Z(2) \geq 12$. Now, assume furthermore that $\dim \mathcal{I}_Z(2) \cap Q_f \geq 11$. Let $\Gamma \subset \mathbb{P}(V)$ be the zero locus of the space of quadrics $I_Z(2) \cap Q_f$. Then $q_f(\Gamma)$ is contained in a $\mathbb{P}^3$, so by Lemma 3.9, $\Gamma$ is either a line and a residual finite subscheme, or $\Gamma$ is finite. Assume first that $\Gamma$ is finite. Then $Z$ spans at least a $\mathbb{P}^4$ in $\mathbb{P}(V)$, since any finite intersection of quadrics in a $\mathbb{P}^3$ has length at most 8. Let $Z_0$ be a maximal length subscheme of $Z$ that spans a $\mathbb{P}^3$ in $\mathbb{P}(V)$. The length of $Z_0$ is then at most 8, and at least 4 since it spans $\mathbb{P}^4$.

The residual scheme $Z_1 = Z \setminus Z_0$ contains a subscheme of length 5 in a plane. By the maximality of $Z_0$, it has at most a subscheme of length 6 in a $\mathbb{P}^3$. Therefore $Z_1$ either has minimal length in its span, in which case the claim follows, or it has length $d$ in a $\mathbb{P}^{d-2}$ with $d = 4, 5$ or 6. If $Z_1$ has length 4 in a plane it is a complete intersection of two curves of degree 2, so again $h^1(\mathcal{I}_Z(2)) = 0$. If $Z_1$ has length 5 and spans a $\mathbb{P}^3$ or length 6 and spans a $\mathbb{P}^4$, it contains a subscheme $Z_2$ of length 3 or 4 in a plane $P_2$. The residual scheme $Z_{1,2}$ to $Z_2$ in $Z_1$ has length 1, 2 or 3. Multiplication by a general linear form $h$ that contains the plane $P_2$ defines an exact sequence of sheaves

$$0 \to \mathcal{I}_{Z_{1,2}}(1) \to \mathcal{I}_{Z_1}(2) \to \mathcal{I}_{H,Z_1}(2) \to 0.$$

Now, $h^1(\mathcal{I}_{Z_{1,2}}(1)) = h^1(\mathcal{I}_{H,Z_1}(2)) = 0$, so we infer $h^1(\mathcal{I}_{Z_1}(2)) = 0$.

We may therefore assume $h^1(\mathcal{I}_{H,Z_0}(3)) > 0$. If $P = \langle Z_0 \rangle$, then, by further restriction, also $h^1(\mathcal{I}_{P,Z_0}(3)) > 0$. If $Z_0$ has length 4 or 5, we may argue as for $Z_1$ above that $h^1(\mathcal{I}_{Z_0}(2)) = 0$ and hence also $h^1(\mathcal{I}_{Z_0}(3)) = 0$. So we may assume that $Z_0$ has length at least 6. Since $Z_0$ is contained in a finite intersection of quadrics, a general net of these quadrics defines a complete intersection $Y$ in $P$ that contains $Z_0$. Then $Y$ has length 8, and contains a subscheme of length at most 2 residual scheme to $Z_0$. If $Z_0 = Y$, then $h^1(\mathcal{I}_{H,Z_0}(3)) = 0$, a contradiction. If $Z_0$ has length 7 it is residual to a point $p$ in $Y$. Let $X$ be a cubic surface that contains $Z_0$ but not $Y$. Then multiplication by the form defining $X$ defines two exact sequences

$$0 \to \mathcal{I}_p \to \mathcal{I}_Y(3) \to \mathcal{I}_{X,Z_0}(3) \to 0$$

Documenta Mathematica 22 (2017) 443–492
and

$$0 \to \mathcal{O}_P \to \mathcal{I}_{P,Z_0}(3) \to \mathcal{I}_{X,Z_0}(3) \to 0.$$  

From the first we deduce that $h^1(\mathcal{I}_{X,Z_0}(3)) = 0$, and so by the second $h^1(\mathcal{I}_{P,Z_0}(3)) = 0$, a contradiction.

If $Z_0$ has degree 6, it contains a subscheme $Z_2$ of length 3 or 4 in a plane $P_2$. The residual scheme $Z_{0,2}$ to $Z_2$ in $Z_0$ has length 2 or 3. Multiplication by the linear form $h$ that defines the plane $P_2$ defines an exact sequence of sheaves

$$0 \to \mathcal{I}_{P,Z_{0,2}}(2) \to \mathcal{I}_{P,Z_0}(3) \to \mathcal{I}_{P_2,Z_2}(3) \to 0.$$

Now, $h^1(\mathcal{I}_{P,Z_{0,2}}(2)) = h^1(\mathcal{I}_{P_2,Z_2}(3)) = 0$, so we infer $h^1(\mathcal{I}_{P,Z_0}(3)) = 0$, a contradiction.

Therefore $\Gamma$ contains a line $\Delta$. Let $Z_\Delta = Z \cap \Delta$. The line $\Delta$ is mapped to a conic $q_f(\Delta)$. If $\dim I_Z(2) \cap Q_f = 12$, then $Z_f = q_f(Z)$ spans only a plane, and the image $q_f(\Gamma)$ has a subscheme of length 3 in a line, unless $Z$ is entirely contained in $\Delta$, i.e., $Z_\Delta = Z$ and $\Gamma = \Delta$. \hfill \Box

**Proof of Proposition 3.1.** Let $[Z] \in VSP(F,10)$. We assume, for contradiction, that $Z$ does not impose independent conditions on cubics. Assuming $f$ is regular and has no partial derivative of rank $\leq 3$, we already proved that $12 \geq \dim I_Z(2) \cap Q_f \geq 11$. By Lemma 3.10, we conclude in both cases that there is a line $\Delta$ such that $I_Z(2) \subset I_\Delta(2)$, so that $I_Z(2) \cap Q_f \subset I_\Delta(2) \cap Q_f$.

Note also that, under the same assumptions on $f$, the image $q_f(\Delta)$ is a conic in a plane that does not have any residual intersection with $X_f = q_f(P(V))$. Thus $\dim I_\Delta(2) \cap Q_f = 12$ and the zero locus of $Q_{f,\Delta} := I_\Delta(2) \cap Q_f$ is $\Delta$.

Since $[Z] \in VSP(F,10)$, there exists a flat family of subschemes

$$(Z_t)_{t \in B}, Z_t \subset \mathbb{P}^5, \text{length } Z_t = 10,$$

where $B$ is a smooth curve, such that $Z_0 = Z$ for some point $0 \in B$ and for general $t \in B$, $Z_t$ is apolar to $f$ and imposes 10 independent conditions to quadrics. The subspace $J_t := I_{Z_t}(2) \subset Q_f$ is thus of codimension 4. Let $J \subset Q_f \cap I_Z(2)$ be the specialization of $J_t$ at $t = 0$. Then $\dim J = 11$ and $J \subset Q_{f,\Delta} = I_\Delta(2) \cap Q_f$, so that $J$ is a hyperplane in $Q_{f,\Delta}$.

On the other hand, note that by semicontinuity of the rank, we have for any $k \geq 0$

$$\operatorname{codim}(S^k V^* \cdot J \subset S^{k+2} V^*) \geq \operatorname{codim}(S^k V^* \cdot J_t \subset S^{k+2} V^*) \geq \operatorname{codim}(I_{Z_t}(k+2) \subset S^{k+2} V^*) = 10.$$  

The contradiction that concludes the proof of Proposition 3.1 is derived from the following statement:

**Lemma 3.11.** Assume $f$ is general. Then for any line $\Delta \subset \mathbb{P}^5$, and for any hyperplane $J \subset Q_{f,\Delta} := I_\Delta(2) \cap Q_f$, we have

$$\operatorname{codim}(S^3 V^* \cdot J \subset S^5 V^*) \leq 9.$$  

*Documenta Mathematica* 22 (2017) 443–492
Furthermore, the locus of smooth cubic fourfolds not satisfying this condition has codimension $> 1$ away from the union of $D_{rk3}$ and $D_{capi}$.

\[ \square \]

**Proof of Lemma 3.11.** The proof has two parts, that both depend on the following property of the zero locus $\Gamma \supseteq \Delta$ of $J$.

Let $\tau_0 : X_0 \to \mathbf{P}^5$ be the blow-up of $\mathbf{P}^5$ along $\Delta$. Then $J$ provides a space $J'$ of sections of $L_0 := \tau_0^*(\mathcal{O}_{\mathbf{P}^5}(2))(-E_\Delta)$ on $X_0$, where $E_\Delta$ is the exceptional divisor of $\tau_0$.

**Sublemma 3.12.** Assume $f$ is regular and has no partial derivative of rank $\leq 3$. Let $J \subset I_{\Delta}(2) \cap Q_f$ be a hyperplane with zero locus $\Gamma \supseteq \Delta$. Let $H \subset \mathbf{P}^5$ be a hyperplane that does not contain $\Delta$. Then the subscheme of $H \cap \Gamma$ that has support on $\Delta$ has length at most 2.

**Proof.** Since $f$ has no partial derivative of rank $\leq 3$, the line $\Delta$ is the zero locus of $Q_{f,\Delta}$, i.e. $Q_{f,\Delta}$ generates $I_{\Delta}(2)$ at any point of $\Delta$. Let $E_{\Delta,x}$ be the fiber over $x = H \cap \Delta$ in $E_\Delta$. Then $E_{\Delta,x} \cong \mathbf{P}^3$ and $L_0|_{E_{\Delta,x}} \cong \mathcal{O}_{\mathbf{P}^3}(1)$. The restriction of the sections $J'$ generates at least a hyperplane of sections in this line bundle, so their zero locus on $E_{\Delta,x}$ is at most a point. So $J$ restricted to $H$, defines a scheme at $x$ that is the intersection of quadrics and is contained in a line, so it has length at most 2. \[ \square \]

Now, we first deal with the case where the zero locus of $J \subset I_{\Delta}(2) \subset S^3V^*$ has a finite subscheme of length at most 3 residual to $\Delta$. In this case, we have the following:

**Sublemma 3.13.** Assume $f$ is regular and has no partial derivative of rank $\leq 3$. Let $J \subset I_{\Delta}(2) \cap Q_f$ be as above, with zero locus $\Gamma \supseteq \Delta$. Assume the scheme $\gamma$ residual to $\Delta$ in $\Gamma$ is finite of length at most 3. Then

\[ (9) \quad S^3V^* \cdot J = I_\Gamma(5). \]

In particular, codim $(S^3V^* \cdot J \subset S^3V^*) \leq 9$.

**Proof.** Let $\tau_0 : X_0 \to \mathbf{P}^5$ be the blow-up of $\mathbf{P}^5$ along $\Delta$, and let, in the notation as above, $\gamma'$ is the zero-locus of $J'$ supported over $\gamma$. As in the proof of Sublemma 3.12, $\gamma'$ intersects the fiber in $E_\Delta$ over any point of $\Delta$ in at most a point. Via the blowup map $\tau_0$, the subscheme $\gamma'$ is therefore isomorphic to the subscheme $\gamma$, and hence finite of length at most 3.

Furthermore, we have

\[ H^0(X_0, \tau_0^*(\mathcal{O}_{\mathbf{P}^5}(2))(-E_\Delta) \otimes I_{\gamma'}) = H^0(X_0, L_0 \otimes I_{\gamma'}) \cong H^0(\mathbf{P}^5, I_{\Gamma}(2)), \]

\[ H^0(X_0, \tau_0^*\mathcal{O}(5)(-E_\Delta) \otimes I_{\gamma'}) \cong H^0(\mathbf{P}^5, I_{\Gamma}(5)). \]

It follows from the last equality that $(9)$ is equivalent to the fact that

\[ H^0(X_0, \tau_0^*\mathcal{O}(3)) \cdot J' = H^0(X_0, \tau_0^*\mathcal{O}(5)(-E_\Delta) \otimes I_{\gamma'}). \]
Assume first that $\gamma'$ is curvilinear. It follows that by successively blowing-up at most three points $x_1$, $x_2$, $x_3$ starting from $x_1 \in X_0$, we get a variety

$$\tau : X \to \mathbb{P}^5, \tau_1 : X \to X_0,$$

with three exceptional divisors $E_i$ corresponding to the $x_i$'s and one exceptional divisor $\tau_1^* E_\Delta$ over $E_\Delta$. The $E_i$ are the pullbacks to $X$ of the exceptional divisor of the blow up at $x_i$ such that the pull-backs $J''$ of the $J'$ gives rise to a base-point free linear system of sections of $L := \tau^* \mathcal{O}(2)(-\tau_1^* E_\Delta - \sum_i E_i)$ on $X$. Furthermore, we have

$$J'' \subset H^0(X, L) \cong H^0(\mathbb{P}^5, \mathcal{I}_T(2)),
H^0(X, \tau^* \mathcal{O}(5)(-\tau_1^* E_\Delta - \sum_i E_i)) \cong H^0(\mathbb{P}^5, \mathcal{I}_T(5)).$$

We are thus reduced to prove that the base-point free linear system

$$J'' \subset H^0(X, \tau^* \mathcal{O}(2)(-\tau_1^* E_\Delta - \sum_i E_i))$$

generates $H^0(X, \tau^* \mathcal{O}(5)(-\tau_1^* E_\Delta - \sum_i E_i))$. This is done by a Koszul resolution argument. The Koszul resolution of the surjective evaluation map

$$J'' \otimes \mathcal{O}_X(-L) \to \mathcal{O}_X,$$

gives us an exact complex with terms $\bigwedge^i J'' \otimes \mathcal{O}_X(-iL), 0 \leq i \leq 5$. We twist this complex by $L' := \tau^* \mathcal{O}(5)(-\tau_1^* E_\Delta - \sum_i E_i)$ and the result then follows from the vanishing

$$H^i(X, (-i - 1)L + L') = 0, i = 1, \ldots, 5.$$

For $i = 5$, we have by (10), (11)

$$-6L + L' = \tau^* \mathcal{O}(-7)(5 \sum_i E_i + 5 \tau_1^* E_\Delta),$$

while

$$K_X = \tau^* \mathcal{O}(-6)(4 \sum_i E_i + 3 \tau_1^* E_\Delta).$$

Thus

$$H^5(X, -6L + L') = H^0(X, \tau^* \mathcal{O}(1)(- \sum_i E_i - 2 \tau_1^* E_\Delta))^*,$$

and the right hand side is 0.

For $i = 4$, we have similarly

$$-5L + L' = \tau^* \mathcal{O}(-5)(4 \sum_i E_i + 4 \tau_1^* E_\Delta),$$

$$H^5(X, -5L + L') = H^0(X, \tau^* \mathcal{O}(2)(- \sum_i E_i - \tau_1^* E_\Delta))^*.$$
Variety of Power Sums and Divisors . . .

\[ H^4(X, -5L + L') = H^1(X, \tau^*\mathcal{O}(-1)(-\tau_1^*E_\Delta))^*, \]
and the right hand side is 0 since it is equal to \( H^1(\mathbb{P}^5, \mathcal{I}_\Delta(-1)) \).

For \( i = 3 \), we have
\[ -4L + L' = \tau^*\mathcal{O}(-3)(3\sum_i E_i + 3\tau_1^*E_\Delta), \]
hence
\[ H^3(X, -4L + L') = H^2(X, \tau^*\mathcal{O}(-3)(\sum_i E_i))^*. \]

Consider the strict transform \( Y \) on \( X \) of a general cubic fourfold whose pullback to \( X_0 \) contains \( \gamma \). Then \( \tau^*\mathcal{O}(-3)(\sum_i E_i) \) is the ideal sheaf of \( Y \). On the other hand \( Y \) is regular so \( H^1(Y, \mathcal{O}_Y) = 0 \), and hence \( H^2(X, \tau^*\mathcal{O}(-3)(\sum_i E_i)) = 0 \).

For \( i = 2 \), we claim that
\[ H^2(X, -3L + L') = H^2(X, \tau^*\mathcal{O}(-1)(2\sum_i E_i + 2\tau_1^*E_\Delta)) = 0. \]

But neither of the two invertible sheaves of exceptional divisors on the right have nonvanishing higher cohomology, so the claim follows.

For \( i = 1 \), we get
\[ H^1(X, -2L + L') = H^1(X, \tau^*\mathcal{O}(1)(\sum_i E_i + \tau_1^*E_\Delta)) = 0, \]
since
\[ H^1(X, \tau^*\mathcal{O}(1)) = H^1(X, E_1) = H^1(X, E_2) = H^1(X, E_\Delta) = H^1(X, \tau_1^*E_\Delta) = 0. \]

When \( \gamma \) is not curvilinear, and thus consists of one point with noncurvilinear schematic structure of length 3, the argument is simpler: Such a scheme \( \gamma \) is the first order neighborhood of a point in a plane. The image \( q_f(\Gamma) = q_f(\gamma) \cup q_f(\Delta) \) spans a \( \mathbb{P}^3 \) and has by assumption no subscheme of length three contained in a line. But \( q_f(\Delta) \) is a conic curve, while \( q_f(\gamma) \) spans a plane that intersects this conic. Therefore there are lines that intersect the conic and \( q_f(\gamma) \) in a subscheme of length 2, a contradiction.

To conclude the proof of Lemma 3.11, we now show

**Sublemma 3.14.** Consider the cubic fourfolds \( F = V(f) \) in the open dense subset
\[ \mathbb{P}(S^3V)_{reg} \setminus (D_{rk3} \cup D_{copl}), \]

*Documenta Mathematica 22 (2017) 443–492*
where $D_{cop}$ is the divisor introduced in Section 2. The subset of such fourfolds for which there exist a line $\Delta \subset P(V^*)$, and a hyperplane $J \subset I_{\Delta}(2) \cap Q_f$, such that the zero locus $\Gamma$ of $J$ has a subscheme residual to $\Delta$ of length $\geq 4$, has codimension $\geq 2$.

Proof. Note first that the scheme $\Gamma$ imposes at most 4 conditions to $Q_f$, since $J \subset Q_f \cap I_{\Gamma}(2)$ has codimension 4 in $Q_f$. Therefore $q_f(\Gamma)$ is contained in the intersection of $X_f$ with a $P^3$, so, by Lemma 3.9, the residual subscheme to $\Delta$ in $\Gamma$ is finite. If it has length $\geq 4$, we can replace $\Gamma$ by a subscheme $\Gamma'$ which is the union of $\Delta$ and a residual scheme $\gamma'$ of finite length 4. And, by Lemma 3.8, $q_f(\Gamma')$ spans a $P^3$. Note that $\Gamma'$, like $\Gamma$, is contained in an intersection of quadrics that is finite residual to the line $\Delta$, so its intersection with a plane is either the line $\Delta$ or the union of the line $\Delta$ and one residual point, or it is a scheme of finite length $\leq 4$. Furthermore, the residual scheme $\gamma'$ is not contained in another line $\Delta'$, since otherwise the union of these two lines would be contained in $\Gamma$. It follows that $\Gamma'$ imposes the maximal number of conditions to the quadrics, namely 7. Hence

$$\dim (I_{\Gamma}(2)) = 14,$$

and $J \subset I_{\Gamma}(2)$ has dimension 11. Since $q_f(\Gamma')$ spans a $P^3$, the intersection $Q_f \cap I_{\Gamma'}(2)$ has dimension 11, so it equals $J$. Now, $Q_f = P(f)^\perp$, so one concludes that

$$\dim (P(f) \cap I_{\Gamma'}(2)^\perp) = 3,$$

where we recall that $P(f)$ is the space of partial derivatives of $f$. The proof of Sublemma 3.14 is done by a dimension count, using (14). We note that as we assumed that $f$ has no partial derivative of rank $\leq 3$, it has no net of partial derivatives singular at a given point by Lemma 2.2. Thus, if $f$ satisfies (14), the space $I_{\Gamma'}(2)^\perp$ is not contained in the space of quadrics singular at a given point. In particular, $\Gamma'$ must span $P(V)$. This is equivalent to the vanishing $H^1(I_{\Gamma'}(1)) = 0$, which we assume from now on.

Equation (14) determines a 3-dimensional subspace $W \subset V^*$, by

$$W(f) = \{ \partial_u f, u \in W \} = P(f) \cap I_{\Gamma'}(2)^\perp.$$

Given $W$ and $\Gamma'$, we define $J_{\Gamma',W} \subset S^3V$ to be the linear space of cubic forms

$$J_{\Gamma',W} := \{ f \in S^3V | W(f) \subset I_{\Gamma'}(2)^\perp = Q_{\Gamma'} \} = (W \cdot I_{\Gamma'}(2))^{\perp}.$$

The space $J_{\Gamma',W}$ contains the space $J_{\Gamma'} := I_{\Gamma'}(3)^\perp$ (which is generated by the cone over the third Veronese embedding of $\Gamma'$) and the space $S^3(W^\perp)$. Consider the subscheme

$$\Gamma'_W := P(W^\perp) \cap \Gamma' \subset P(V).$$

and assume first that $\Gamma'_W = \emptyset$. In this case, we claim that

$$J_{\Gamma',W} = S^3(W^\perp) \oplus J_{\Gamma'},$$

where $D_{cop}$ is the divisor introduced in Section 2. The subset of such fourfolds for which there exist a line $\Delta \subset P(V^*)$, and a hyperplane $J \subset I_{\Delta}(2) \cap Q_f$, such that the zero locus $\Gamma$ of $J$ has a subscheme residual to $\Delta$ of length $\geq 4$, has codimension $\geq 2$. 

Proof. Note first that the scheme $\Gamma$ imposes at most 4 conditions to $Q_f$, since $J \subset Q_f \cap I_{\Gamma}(2)$ has codimension 4 in $Q_f$. Therefore $q_f(\Gamma)$ is contained in the intersection of $X_f$ with a $P^3$, so, by Lemma 3.9, the residual subscheme to $\Delta$ in $\Gamma$ is finite. If it has length $\geq 4$, we can replace $\Gamma$ by a subscheme $\Gamma'$ which is the union of $\Delta$ and a residual scheme $\gamma'$ of finite length 4. And, by Lemma 3.8 (3), we may assume $q_f(\Gamma')$ spans a $P^3$. Note that $\Gamma'$, like $\Gamma$, is contained in an intersection of quadrics that is finite residual to the line $\Delta$, so its intersection with a plane is either the line $\Delta$ or the union of the line $\Delta$ and one residual point, or it is a scheme of finite length $\leq 4$. Furthermore, the residual scheme $\gamma'$ is not contained in another line $\Delta'$, since otherwise the union of these two lines would be contained in $\Gamma$. It follows that $\Gamma'$ imposes the maximal number of conditions to the quadrics, namely 7. Hence

$$\dim (I_{\Gamma}(2)) = 14,$$

and $J \subset I_{\Gamma}(2)$ has dimension 11. Since $q_f(\Gamma')$ spans a $P^3$, the intersection $Q_f \cap I_{\Gamma'}(2)$ has dimension 11, so it equals $J$. Now, $Q_f = P(f)^\perp$, so one concludes that

$$\dim (P(f) \cap I_{\Gamma'}(2)^\perp) = 3,$$

where we recall that $P(f)$ is the space of partial derivatives of $f$. The proof of Sublemma 3.14 is done by a dimension count, using (14). We note that as we assumed that $f$ has no partial derivative of rank $\leq 3$, it has no net of partial derivatives singular at a given point by Lemma 2.2. Thus, if $f$ satisfies (14), the space $I_{\Gamma'}(2)^\perp$ is not contained in the space of quadrics singular at a given point. In particular, $\Gamma'$ must span $P(V)$. This is equivalent to the vanishing $H^1(I_{\Gamma'}(1)) = 0$, which we assume from now on.

Equation (14) determines a 3-dimensional subspace $W \subset V^*$, by

$$W(f) = \{ \partial_u f, u \in W \} = P(f) \cap I_{\Gamma'}(2)^\perp.$$

Given $W$ and $\Gamma'$, we define $J_{\Gamma',W} \subset S^3V$ to be the linear space of cubic forms

$$J_{\Gamma',W} := \{ f \in S^3V | W(f) \subset I_{\Gamma'}(2)^\perp = Q_{\Gamma'} \} = (W \cdot I_{\Gamma'}(2))^{\perp}.$$

The space $J_{\Gamma',W}$ contains the space $J_{\Gamma'} := I_{\Gamma'}(3)^\perp$ (which is generated by the cone over the third Veronese embedding of $\Gamma'$) and the space $S^3(W^\perp)$. Consider the subscheme

$$\Gamma'_W := P(W^\perp) \cap \Gamma' \subset P(V).$$

and assume first that $\Gamma'_W = \emptyset$. In this case, we claim that

$$J_{\Gamma',W} = S^3(W^\perp) \oplus J_{\Gamma'},$$
so that $\dim J'\cdot W = 18$. Assuming the claim, we now observe that elements

$$f \in J'\cdot W = S^3(W^\perp) \oplus J'$$

fill-in, when the pair $(\Gamma', W)$ deforms, staying in general position, the divisor $D_{opt}$ of Section 2. Indeed, the general $\Gamma'$ is the disjoint union of a line $\Delta = \mathbf{P}(U)$ and 4 points $x_1, \ldots, x_4$. Then $J' = \mathbf{P}(S^3U \oplus \langle x_1^3, \ldots, x_4^3 \rangle)$ and thus $f \in S^3(W^\perp) \oplus J'$ belongs to $S^3(W^\perp) + S^3U + \langle x_1^3, \ldots, x_4^3 \rangle$. The component of $f$ lying in $S^3(W^\perp)$ is the sum of 4 cubes of coplanar linear forms, and the component of $f$ lying in $S^3U$ is the sum of 2 cubes. Thus $f$ is the sum of 10 cubes of linear forms, 4 of which are coplanar.

In order to prove formula (15), we dualize it and note that it is equivalent to the equality

$$W \cdot I_{\Gamma'}(2) = (W \cdot S^2V^*) \cap I_{\Gamma'}(3).$$

The right hand side is equal to $I_{\Gamma' \cup \mathbf{P}(W^\perp)}(3)$. As $\Gamma' \cap \mathbf{P}(W^\perp) = \emptyset$, the Koszul resolution of the ideal sheaf $I_{\mathbf{P}(W^\perp)}$ remains exact after tensoring by $I_{\Gamma'}$, which gives the following resolution of $I_{\Gamma' \cup \mathbf{P}(W^\perp)}$:

$$0 \to \bigwedge^3 W \otimes I_{\Gamma'}(-3) \to \bigwedge^2 W \otimes I_{\Gamma'}(-2) \to W \otimes I_{\Gamma'}(-1) \to I_{\Gamma' \cup \mathbf{P}(W^\perp)} \to 0.$$

Twisting with $\mathcal{O}(3)$ and applying the vanishings $H^1(I_{\Gamma'}(1)) = 0$ and $H^2(I_{\Gamma'}) = 0$, we get the desired equality $W \cdot I_{\Gamma'}(2) = I_{\Gamma' \cup \mathbf{P}(W^\perp)}(3)$.

To conclude the proof of Sublemma 3.14, it only remains to prove the following claim:

**Claim 3.15.** The set of cubic fourfolds in the open set $\mathbf{P}^{55}_{reg} \setminus D_{rk3} := \mathbf{P}(S^3V)_{reg} \setminus D_{rk3}$ satisfying (14) for a pair $(W, \Gamma')$ with $\Gamma'_{W} = \Gamma' \cap \mathbf{P}(W^\perp) \neq \emptyset$ has codimension $\geq 2$.

\[ \square \]

**Proof of Claim 3.15.** Recall, from above, that $\Gamma'$ contains a line $\Delta$ and spans $\mathbf{P}^5$. Also, since $q_3(\Gamma')$ spans a $\mathbf{P}^3$ and contains no subscheme of length 3 in a line, every component of $\Gamma'$ that is not supported on $\Delta$ is curvilinear. Consider the intersection $\Gamma'_{W} = \Gamma' \cap \mathbf{P}(W^\perp)$.

If $\Gamma'_{W}$ contains $\Delta$, then, since it is the intersection of quadrics and is finite residual to $\Delta$, the residual scheme to $\Delta$ in $\Gamma'_{W}$ is at most a point.

If $\Gamma'_{W}$ intersects $\Delta$ only in a point $x$, then $\Gamma'_{W} \cup \Delta$ spans at most a $\mathbf{P}^3$, so $\Gamma'$ has a scheme of length at least 2 residual to $\Gamma'_{W} \cup \Delta$. By Sublemma 3.12, the scheme $\Gamma'_{W}$ has a component of length at most 2 supported on $x$ and a residual closed point $x'$.

If $\Gamma'_{W}$ does not intersect the line $\Delta$, then $\Gamma'_{W}$ is curvilinear and has length at most 3.

We observe that in each of the listed situations, if $X, Y \in W$ are generically chosen, and $\mathbf{P}^3_{X, Y} \supseteq \mathbf{P}(W^\perp)$ is defined by $X$ and $Y$, we have

$$\Gamma' \cap \mathbf{P}^3_{X, Y} = \Gamma' \cap \mathbf{P}(W^\perp) = \Gamma'_{W}.$$
We want to estimate the dimension of $J^{Γ',W} = (W \cdot I_{Γ'}(2))^\perp$, or equivalently of $W \cdot I_{Γ'}(2)$, since
\[
\dim J^{Γ',W} = 56 - \dim (W \cdot I_{Γ'}(2)).
\]
We consider the exact sequence
\[
0 \to \langle X, Y \rangle \cdot I_{Γ'}(2) \to W \cdot I_{Γ'}(2) \to W \cdot I_{Γ'}(2)|_{P^3_{X,Y}} \to 0.
\]
and observe that $\dim W \cdot I_{Γ'}(2)|_{P^3_{X,Y}} = \dim I_{Γ'}(2)|_{P^3_{X,Y}}$. Therefore
\[
(17) \quad \dim (W \cdot I_{Γ'}(2)) = \dim \langle X, Y \rangle \cdot I_{Γ'}(2) + \dim I_{Γ'}(2)|_{P^3_{X,Y}}.
\]
Furthermore, consider the space of linear forms $[I_{Γ'}(2) : \langle X, Y \rangle] \subset V$. Multiplication by the matrix $(X, -Y)$ and $(Y, X)^t$ respectively defines an exact sequence
\[
0 \to [I_{Γ'}(2) : \langle X, Y \rangle] \to I_{Γ'}(2) \oplus I_{Γ'}(2) \to \langle X, Y \rangle \cdot I_{Γ'}(2) \to 0.
\]
From this sequence, and the fact (13) that $\dim I_{Γ'}(2) = 14$, we get
\[
\dim \langle X, Y \rangle \cdot I_{Γ'}(2) = 2 \dim I_{Γ'}(2) - \dim [I_{Γ'}(2) : \langle X, Y \rangle] = 28 - \dim [I_{Γ'}(2) : \langle X, Y \rangle].
\]
Putting this equality together with the equation (17) we get:
\[
\dim J^{Γ',W} = 28 + \dim [I_{Γ'}(2) : \langle X, Y \rangle] - \dim I_{Γ'}(2)|_{P^3_{X,Y}}.
\]
We make now a case-by-case analysis. Recall that if the scheme $Γ'_{Γ'}$ has finite length, this length is $\leq 3$ and if it contains the line $Δ$, it contains at most one reduced residual point.

1. If $Γ'_{Γ'} = [l]$ is a reduced point on $Δ = P(U)$, which is not the support of an embedded point, then $\dim [I_{Γ'}(2) : \langle X, Y \rangle] = 0$ and $\dim I_{Γ'}(2)|_{P^3_{X,Y}} = 9$, so we get $\dim J^{Γ',W} = 19$. The parameter space for such $(W, Γ)'s$ has dimension $7 + 28 = 35$, so the subset of $P^{55}_{reg}$ satisfying equation (14) with this condition on $(W, Γ)$ has dimension $\leq 35 + 18 = 53$.

2. If $Γ'_{Γ'} = [l]$ is a reduced point on $Δ = P(U)$, the support of an embedded point, then $\dim [I_{Γ'}(2) : \langle X, Y \rangle] = 1$ and $\dim I_{Γ'}(2)|_{P^3_{X,Y}} = 9$. Thus $\dim J^{Γ',W} = 20$. As $Γ'$ has an embedded point on $Δ$, the parameter space for $Γ'$ has dimension 27, so the parameter space for such $(W, Γ)'s$ has dimension $7 + 27 = 34$. Thus the subset of $P^{55}_{reg}$ satisfying equation (14) with this condition on $(W, Γ)$ has dimension $\leq 34 + 19 = 53$.

3. If $Γ'_{Γ'} = [l]$ is a reduced point not in $Δ$, then $\dim [I_{Γ'}(2) : \langle X, Y \rangle] = 1$ and $\dim I_{Γ'}(2)|_{P^3_{X,Y}} = 9$, so we get $\dim J^{Γ',W} = 20$. The parameter space for such $(W, Γ)'s$ has dimension $6 + 28 = 34$, so the subset of $P^{55}_{reg}$ satisfying equation (14) with this condition on $(W, Γ)$ has dimension $\leq 34 + 19 = 53$. 

Documenta Mathematica 22 (2017) 443–492
(4) If $\Gamma'_W$ is a subscheme of length 2 that intersects $\Delta$ in one point, which is not the support of an embedded point, then $\dim [I_{\Gamma'}(2) : (X, Y)] = 1$ and $\dim I_{\Gamma'}(2)|_{P^3_{X,Y}} = 8$, so we get $\dim J^{\Gamma', W} = 21$. The parameter space for such $(W, \Gamma')$'s has dimension $4 + 28 = 32$, so the subset of $P^5_{reg}$ satisfying equation (14) with this condition on $(W, \Gamma)$ has dimension $\leq 32 + 20 = 52$.

(5) If $\Gamma'_W$ is a subscheme of length 2 that intersects $\Delta$ in one point, which is the support of an embedded point, then $\dim [I_{\Gamma'}(2) : (X, Y)] = 2$ and $\dim I_{\Gamma'}(2)|_{P^3_{X,Y}} = 8$, so we get $\dim J^{\Gamma', W} = 22$. The parameter space for such $(W, \Gamma')$'s has dimension $3 + 27 = 30$, so the subset of $P^5_{reg}$ satisfying equation (14) with this condition on $(W, \Gamma)$ has dimension $\leq 30 + 21 = 51$.

(6) If $\Gamma'_W = z^2$ is a subscheme of length 2 that does not intersect $\Delta$, then $\dim [I_{\Gamma'}(2) : (X, Y)] = 2$ and $\dim I_{\Gamma'}(2)|_{P^3_{X,Y}} = 7$, so we get $\dim J^{\Gamma', W} = 22$. The parameter space for such $(W, \Gamma')$'s has dimension $28$, so the subset of $P^5_{reg}$ satisfying equation (14) with this condition on $(W, \Gamma)$ has dimension $\leq 23 + 28 = 51$.

(7) If $\Gamma'_W = \Delta$, then $\dim [I_{\Gamma'}(2) : (X, Y)] = 3$ and $\dim I_{\Gamma'}(2)|_{P^3_{X,Y}} = 7$, so we get $\dim J^{\Gamma', W} = 23$. The parameter space for such $(W, \Gamma')$'s has dimension $27$, so the subset of $P^5_{reg}$ satisfying equation (14) with this condition on $(W, \Gamma)$ has dimension $\leq 22 + 23 = 50$.

(8) If $\Gamma'_W$ is a subscheme of length 3 that does not intersect $\Delta$, then $\dim [I_{\Gamma'}(2) : (X, Y)] = 3$

and $\dim I_{\Gamma'}(2)|_{P^3_{X,Y}} = 7$, so we get $\dim J^{\Gamma', W} = 24$. The parameter space for such $(W, \Gamma')$'s has dimension $28$, so the subset of $P^5_{reg}$ satisfying equation (14) with this condition on $(W, \Gamma)$ has dimension $\leq 23 + 28 = 51$.

(9) If $\Gamma'_W$ is a subscheme of length 3 that intersects $\Delta$ in a point $[l]$, which is the support of an embedded point, then $\dim [I_{\Gamma'}(2) : (X, Y)] = 3$ and $\dim I_{\Gamma'}(2)|_{P^3_{X,Y}} = 7$, so we get $\dim J^{\Gamma', W} = 24$. The parameter space for such $(W, \Gamma')$'s has dimension $27$, so the subset of $P^5_{reg}$ satisfying equation (14) with this condition on $(W, \Gamma)$ has dimension $\leq 22 + 23 = 50$.

(10) If $\Gamma'_W$ is a subscheme of length 3 that intersects $\Delta$ in a point $[l]$, which is not the support of an embedded point, then $\dim [I_{\Gamma'}(2) : (X, Y)] = 2$ and $\dim I_{\Gamma'}(2)|_{P^3_{X,Y}} = 7$, so we get $\dim J^{\Gamma', W} = 23$. The parameter space for such $(W, \Gamma')$'s has dimension $1 + 28 = 29$, so the subset of $P^5_{reg}$ satisfying equation (14) with this condition on $(W, \Gamma)$ has dimension $\leq 22 + 29 = 51$.

(11) If $\Gamma'_W$ is the union of the line $\Delta$ and an embedded point, then $\dim [I_{\Gamma'}(2) : (X, Y)] = 3$ and $\dim I_{\Gamma'}(2)|_{P^3_{X,Y}} = 6$, so we get
\dim \mathcal{V}^W = 25. The parameter space for such \((W, \Gamma)\)'s has dimension 28, so the subset of \(\mathbb{P}^{55}_{\text{reg}}\) satisfying equation (14) with this condition on \((W, \Gamma)\) has dimension \(\leq 24 + 28 = 52\).

This proves the claim.

\[ \square \]

The proof of Lemma 3.11, hence also of Proposition 3.1, is finished.

\[ \square \]

3.2. SYZYGIES. Recall that the cactus rank of a cubic fourfold \(F = V(f)\) is the minimal length of an apolar subscheme (Definition 3.2). We consider the syzygies of the ideal \(I_f\), and give below a partial characterization of cubic fourfolds of cactus rank < 10, which we will use to prove Proposition 4.1 in the next section.

For a cubic fourfold \(F \subset \mathbb{P}(V^*)\), let \(V_{10}(F) \subset \mathbb{P}(V)\) be the union of subschemes of length 10 which are apolar to \(F\). We shall show, in Lemma 3.21, that when \(F\) is general and of cactus rank 10, then \(V_{10}(F)\) is a hypersurface of degree 9.

As suggested to us by Hans Christian von Bothmer, to find the equation of \(V_{10}(F)\), when it is a hypersurface, we study the syzygies of the apolar ideal \(I_f\) and compare it with syzygies of the ideal of subschemes of length 9 and 10.

We are interested in the graded Betti numbers for the minimal free resolution of the ideal \(I_f\) for a general \(f\), and for the ideal of a general set of 9 and 10 points.

**Example 3.16.** The Betti numbers in the following examples have been computed with Macaulay2 [18].

(1) Let \(f \in \mathbb{C}[x_0, ..., x_5]\) be the cubic form

\[
f = 2x_1^2x_2 - 2x_0x_2^2 - 2x_1^2x_3 - 2x_0x_1x_5 + 2x_1x_2x_5
+ x_2^2x_5 + x_2x_3x_5 + 3x_1x_4x_5 + x_3^2x_5 + 3x_0x_5 + x_3x_5^2
\]

Then the resolution of \(I_f\) has Betti numbers:

\[
\begin{array}{cccccccc}
1 & - & - & - & - & - & - & - \\
15 & 35 & 21 & - & - & - & - & - \\
- & 21 & 35 & 15 & - & - & - & - \\
\end{array}
\]

(2) Let \(Z_6\) be the 6 coordinate points in \(\mathbb{P}^5\), then the resolution of the ideal of the 9 points \(Z_9 = Z_6 \cup \{(1:1:1:0:0),(0:0:1:-1:-1:1),(1:-1:0:0:1:1)\}\) in \(\mathbb{P}^5\) has Betti numbers

\[
\begin{array}{cccccccc}
1 & - & - & - & - & - & - & - \\
- & - & 6 & 10 & 3 & - & - & - \\
\end{array}
\]

\[ \]
(3) The resolution of the ideal of the 10 points $Z_9 \cup \{(0 : 1 : -1 : -1 : 0 : 1)\}$ in $\mathbb{P}^5$ has Betti numbers

\[
\begin{array}{ccccccc}
1 & - & - & - & - & - \\
- & 11 & 20 & 5 & - & - \\
- & - & - & 16 & 15 & 4 \\
\end{array}
\]

Remark 3.17. The graded Betti numbers in the three resolutions of Example 3.16 are clearly minimal for apolar ideals of cubic forms and for ideals of 9 (resp. 10) points in $\mathbb{P}^5$. By semicontinuity we conclude that the Betti numbers are the same as in these examples for a general cubic form, and for the ideal of 9 (resp. 10) general points in $\mathbb{P}^5$.

Lemma 3.18. If $f$ is a cubic form with no partials of rank $\leq 3$, then $f$ has cactus rank $\geq 9$. If furthermore the minimal free resolution of the apolar ideal $I_f$ has Betti numbers

\[
\begin{array}{ccccccc}
1 & - & - & - & - & - \\
- & 15 & 35 & 21 & - & - \\
- & - & - & 21 & 35 & 15 & 1 \\
\end{array}
\]

and $f$ has cactus rank 9, then the $(35 \times 21)$-matrix $M_2$ of linear second order syzygies has generic rank at most 20. In other words, if $f$ has no partial derivative of rank $\leq 3$, the apolar ideal $I_f$ has Betti numbers as above and the matrix $M_2$ has generic rank 21, then $f$ has cactus rank 10.

Proof. Since $f$ has no partial derivatives of rank $\leq 3$, the map $q_f : \mathbb{P}(V) \to X_f$ is a smooth embedding and $X_f$ has no trisecant lines, by Lemma 3.8. Let $Z$ be an apolar subscheme of length at most 8. Since $I_Z(2) \subset Q_f = I_f(2)$ and $Q_f \subset S^2 V$ has codimension 6, the rank of the restriction map $Q_f \to H^0(\mathcal{O}_Z(2))$ is at most 2. Hence $Z_f = q_f(Z)$ is contained in a line, and $X_f$ would have a trisecant line, a contradiction. Therefore $f$ has cactus rank at least 9.

Assume next, $f$ has cactus rank 9 computed by an apolar subscheme $Z \subset \mathbb{P}(V)$ that consists of 9 general points. We consider the Gale transform of $Z$ (cf. [11]). The Gale transform $Z'$ of $Z$ is a set of 9 points in a plane, and $Z'$ is general since $Z$ is general. In particular we may assume that $Z'$ lies on a unique smooth cubic curve. By [11, Corollary 3.2], the set of 9 points $Z'$ itself lies on this curve reembedded as an elliptic sextic curve $E_Z$ in $\mathbb{P}(V)$. The Betti numbers of the minimal free resolution of the ideal of $E_Z$ are

\[
\begin{array}{ccccccc}
1 & - & - & - & - \\
- & 9 & 16 & 9 & - \\
- & - & - & - & 1 \\
\end{array}
\]

Since $I_{E_Z} \subset I_Z$ and $I_Z \subset I_f$, by assumption, we get that $I_{E_Z} \subset I_f$, i.e. the elliptic sextic curve $E_Z$ is apolar to $f$. The inclusion of the resolution of $I_{E_Z}$ in the resolution of $I_f$ displays a third order syzygy of the ideal $I_{E_Z}$ that is a third order syzygy for the linear strand of the resolution of the ideal $I_f$. In the resolution of $I_f$ the matrix $M_2$ therefore has generic rank at most 20.
It remains to consider any cubic form $f$ of cactus rank 9 and no partials of rank at most 3. Let $Z$ be a length 9 subscheme apolar to $f$. Now, by Remark 3.3, the scheme $Z$ is locally Gorenstein and the limit of smooth schemes of length 9, the form $f$ is likewise a limit of forms of cactus rank 9 with a smooth apolar scheme of length 9. Therefore, by the previous argument, the matrix $M_2$ in the resolution of $I_f$ is the limit of matrices of generic rank at most 20, so $M_2$ also has generic rank at most 20.

\[ \square \]

We analyze further the syzygies of elliptic normal sextic curves, to find the locus in $\mathbf{P}(V)$ where the matrix $M_2$ in the resolution of $I_f$ drops rank. First, an elliptic normal sextic curve $E$ lies in a smooth Veronese surface: any of the four linear systems $|D|$ of degree 3 on $E$ such that $|2D|$ is the linear system of hyperplane sections of $E \subset \mathbf{P}(V)$, is the linear system of conic sections of $E$ in a smooth Veronese surface in $\mathbf{P}(V)$.

Lemma 3.19. Let $E$ be an elliptic normal sextic curve in $\mathbf{P}^5$ and let

\[ p \in \mathbf{P}(V) \setminus E. \]

Then the ideal of $E \cup \{p\}$ has a unique second order linear syzygy that vanishes at $p$.

If, in addition, $p$ is not contained in the secant variety of any of the four Veronese surfaces containing $E$, then the syzygy has rank 5 and no ideal strictly contained in the ideal of $E \cup \{p\}$ has this syzygy.

If $p \in \Sigma \setminus E$, where $\Sigma$ is a Veronese surface that contains $E$, then the second order linear syzygy that vanishes at $p$ is a syzygy for $I_\Sigma$, but no ideal strictly contained in $I_\Sigma$.

Proof. Let $p$ be in $\mathbf{P}(V) \setminus E$. The minimal free resolution of $I_E$ is symmetric with Betti numbers

\[ 1 \quad - \quad - \quad - \quad - \]

\[ - \quad 9 \quad 16 \quad 9 \quad - \]

\[ - \quad - \quad - \quad - \quad 1 \]

The third order syzygy is therefore nonzero at the point $p$ outside $E$, and defines a unique second order syzygy that vanishes at $p$.

This syzygy is a syzygy among at most 5 first order linear syzygies that also vanishes at $p$, and finally, these first order syzygies are linear syzygies among quadrics in the ideal of $E$ that vanish at $p$. Therefore the ideal of $I_{E \cup \{p\}}$ has a second order linear syzygy vanishing at $p$.

The secant variety of $E$ is the intersection of a pencil of determinantal cubic hypersurfaces that are singular along $E$ (see [12] Theorem 1.3, Lemma 2.9). In fact, these hypersurfaces are defined by determinants of $(3 \times 3)$-matrices with linear entries that have rank one along $E$. Since $E$ is smooth, all the linear entries are nonzero. Four of the cubic hypersurfaces are secant varieties of Veronese surfaces that contain $E$. If $p$ is not on any of these four hypersurfaces, then $p$ is not on the secant variety of $E$, and there is a unique cubic determinantal hypersurface $Y$ that is singular along $E$ and contains $p$. We may
assume that this hypersurface is defined by the determinant of the \((3 \times 3)\)-
matrix \( A = \begin{pmatrix} a_0 & a_1 & a_2 \\ a_3 & a_4 & a_5 \\ a_6 & a_7 & a_8 \end{pmatrix} \) with linear entries \( a_i \). Since \( p \) is not on any of the
four secant varieties of a Veronese surface containing \( E \), the matrix \( A \) is not symmetric, so \( p \) is in a unique plane in each of the two nets of planes in \( Y \).
In particular we may assume that \( p = V(a_0, a_1, a_2, a_4, a_7) \). Then the ideal of
\( E \cup \{ p \} \) is generated by all the \((2 \times 2)\)-minors of \( A \) except \( a_3a_8 - a_6a_5 \), i.e. the quadrics
\[
I_{E\cup\{p\}} = (a_1a_3 - a_0a_4, a_2a_3 - a_0a_5, a_4a_2 - a_1a_5, a_4a_1 - a_0a_7, a_2a_6 - a_0a_8, \\
a_3a_6 - a_3a_7, a_2a_7 - a_1a_8, a_5a_7 - a_4a_8).
\]
These quadrics have the following matrices of first and second order linear syzygies that vanish at \( p \):
\[
S_1 = \begin{pmatrix}
-a_2 & 0 & a_7 & 0 & 0 \\
0 & a_0 & a_7 & 0 \\
-a_0 & 0 & -a_4 & a_7 \\
0 & a_1 & 0 & a_4 \\
0 & a_2 & 0 & 0 \\
0 & 0 & -a_0 & 0 \\
0 & 0 & 0 & a_0 \\
0 & 0 & 0 & a_1 \\
0 & 0 & 0 & -a_1 \\
\end{pmatrix}
\quad \text{and} \quad
S_2 = \begin{pmatrix}
a_7 & -a_7 \\
a_4 & -a_2 \\
a_1 & a_0 \\
0 & 0 \\
\end{pmatrix},
\]
i.e.
\[
I_{E\cup\{p\}} \cdot 2 \cdot S_1 = S_1 \cdot S_2 = 0.
\]
The rows of the matrix \( S_1 \) have no constant syzygies, so there are no ideal properly contained in \( I_{E\cup\{p\}} \) with the second order linear syzygy, \( S_2 \), among its quadrics.
Now, if the matrix above is symmetric, i.e. \( a_1 = a_3, a_2 = a_6, a_5 = a_7 \), it has rank one along a Veronese surface \( \Sigma \). Therefore, for each point \( p \in \Sigma \), there is an inclusion \( I_p \subset I_{E\cup\{p\}} \). The quadrics in \( I_{E\cup\{p\}} \) in the non-symmetric case reduces to the quadrics in \( I_\Sigma \). If \( p = V(a_0, a_1, a_2, a_4, a_7) \in \Sigma \), the above displayed second order syzygy remains a second order linear syzygy among the quadrics in \( I_\Sigma \), and as in the non-symmetric case, no proper ideal contained in \( I_\Sigma \) has this second order linear syzygy.

\[\square\]
Assume now that \( Z \) is a set of 10 points that is apolar to a cubic fourfold \( F \) of rank 10, and that a subset \( Z_0 \subset Z \) of 9 points lies in an elliptic normal sextic curve \( E \). By Lemma 3.19, the ideal of \( E \cup Z \), and hence also \( I_Z \), has a second order syzygy that vanishes in the point \( p = Z \setminus Z_0 \) so the matrix \( M_2 \) in the resolution of \( I_F \) has rank at most 20 at \( p \).
Furthermore, assume that the set \( Z_0 \subset E \) of 9 points in \( \mathbb{P}(V) \) is the base locus of a pencil of elliptic sextic curves \( \{ E_\lambda \} \) on a Veronese surface, and that the point \( p \) is not contained in the secant variety of this Veronese surface. Then,

Documenta Mathematica 22 (2017) 443–492
for a general curve $E_3$ in the pencil, the second order linear syzygy for the ideal of $E_0 \cup Z$ determines the curve. Therefore there is a pencil of second order syzygies for $I_Z$ that vanishes at $p = Z \setminus Z_0$. Hence, we conclude that the matrix $M_2$ in the resolution of $I_f$ has rank at most 19 at $p$.

Let $F$ be a cubic fourfold defined by a form $f$ of rank 10 and consider the incidence

$$I_{VSP} = \{(p, [Z]) | p \in Z \} \subset \mathbf{P}(V) \times VSP(F, 10).$$

Then, by definition, $V_{10}(F) \subset \mathbf{P}(V)$ is the image of $I_{VSP}$ under the first projection $I_{VSP} \rightarrow \mathbf{P}(V)$.

**Corollary 3.20.** Let $f$ be a cubic form of rank 10 with no partial derivatives of rank $\leq 3$ and Betti numbers

$$
\begin{array}{cccccccc}
1 & - & - & - & - & - & - & - \\
- & 15 & 35 & 21 & - & - & - & - \\
- & - & - & - & 21 & 35 & 15 & - \\
- & - & - & - & - & - & - & 1
\end{array}
$$

for the apolar ideal $I_f$. Assume that there exist a set $Z$ of 10 points apolar to $f$, and that a subset $Z_0 \subset Z$ of 9 points lie on an elliptic sextic curve $E_{Z_0}$, while the point $p = Z \setminus Z_0$ does not lie on the secant variety of any Veronese surface that contains $E_{Z_0}$. Then the $(35 \times 21)$-matrix $M_2$ of linear second order syzygies has rank at most 20 along $V_{10}(F)$. Furthermore, $M_2$ has rank at most 19 at every point $p \in Z \subset \mathbf{P}(V)$ such that the subscheme $Z_0$ is contained in a pencil of elliptic sextic curves on a Veronese surface.

**Proof.** The first condition on $Z_0$ and $Z$ is clearly an open condition in $VSP(F, 10)$, so $M_2$ has rank at most 20 along a Zariski open set of $V_{10}(F)$, hence everywhere along $V_{10}(F)$. Similarly the second condition on $Z_0$ and $Z$ is open among sets of points $Z$ such that the subset $Z_0$ is contained in a pencil of elliptic sextic curves on a Veronese surface, so the second part of the Corollary follows.

\[ \square \]

**Lemma 3.21.** (von Bothmer [5]) Let $f$ be a cubic form whose apolar ideal $I_f$ has a minimal free resolution with Betti numbers

$$
\begin{array}{cccccccc}
1 & - & - & - & - & - & - & - \\
- & 15 & 35 & 21 & - & - & - & - \\
- & - & - & - & 21 & 35 & 15 & - \\
- & - & - & - & - & - & - & 1
\end{array}
$$

Then the $(35 \times 21)$-matrix $M_2$ of linear second order syzygies has rank at most 20 either on all of $\mathbf{P}(V)$ or on a hypersurface $Y_F$. In the second case, $V_{10}(F)$ is equal to $Y_F$ and has degree 9 if $M_2$ has rank 20 at a general point of $Y_F$.

**Proof.** Consider the linear strand of the resolution of $I_f$ with Betti numbers

$$
\begin{array}{cccccccc}
1 & - & - & - & - \\
- & 15 & 35 & 21 & -
\end{array}
$$

\[ \square \]
evaluated at a general point. The first map has kernel of dimension 14. Therefore the corank of the third map \( \varphi_{M_2} \) is at least 14. If the linear strand is exact at a general point, then the rank of the third map drops along a hypersurface. We compute the degree of this hypersurface by restricting the linear strand to a general line \( L \subset \mathbb{P}(V) \). This restriction of the linear strand is a complex

\[
0 \leftrightarrow \mathcal{O}_L \leftrightarrow 15\mathcal{O}_L(-2) \leftrightarrow 35\mathcal{O}_L(-3) \leftrightarrow 21\mathcal{O}_L(-4) \leftrightarrow 0
\]

that is exact, except at \( 35\mathcal{O}_L(-3) \). The kernel of the first map is a vector bundle \( E_1 \) of rank 14 and first Chern class \( c_1(E_1) = -30 \) on \( L \). Therefore, the second map factors into a surjective map \( E_1 \leftrightarrow 35\mathcal{O}_L(-3) \) with kernel a vector bundle \( E_2 \) of rank 21 with first Chern class \( c_1(E_2) = 35 \cdot (-3) - (-30) = -75 \) on \( L \). The third map of the linear strand, defined by the restriction of \( \varphi_{M_2} \) to \( L \), factors through a vector bundle map \( E_2 \leftrightarrow 21\mathcal{O}_L(-4) \) between two bundles of rank 21. The determinant of this bundle map, since it is assumed to be nonzero, defines a divisor whose class is the difference of the first Chern classes of the two bundles, i.e. of degree \( -75 + 21 \cdot (-4) = 9 \) on \( L \). So \( \varphi_{M_2} \) either has rank at most 20 on all of \( \mathbb{P}(V) \) or it has rank at most 20 on a hypersurface of degree 9.

For the last statement, we already proved in Corollary 3.20 that the hypersurface \( V_{10}(F) \subset \mathbb{P}(V) \) is contained in the determinantal hypersurface \( Y_F \) of points where \( M_2 \) has rank at most 20. On the other hand, one can exhibit \( F \) for which \( Y_F \) is irreducible (cf. Proposition 4.1). Hence for such an \( F \), \( V_{10}(F) \) must be equal to \( Y_F \), which implies the same result for any \( F \).

\[ \square \]

**Remark 3.22.** The general cubic fourfold \( F \) in the divisor \( D_{IR} \) has rank 10, while \( V_{10}(F) \) is a Pfaffian cubic hypersurface (cf. [15, Lemma 3.9 and Proposition 3.15]). In this case the \((35 \times 21)\)-matrix \( M_2 \) has rank 18 at a general point of \( V_{10}(F) \).

**Lemma 3.23.** Let \( f \in S^3V \) be a cubic form whose apolar ideal \( I_f \) has a minimal free resolution with Betti numbers

\[
\begin{array}{cccccc}
1 & & & & & \\
& & 15 & 35 & 21 & \\
& & & & 21 & 35 \ 15 \\
& & & & & 1
\end{array}
\]

If the \((35 \times 21)\)-matrix \( M_2 \) of linear second order syzygies has rank 21 at a general point and rank 20 at some point, then \( V_{10}(F) \) is singular along the set of points \( [l] \in \mathbb{P}(V) \) for which \( f - l^3 \) has rank 9 and the matrix \( M_2 \) has rank at most 19, in particular at the points \( [l] \) for which \( f - l^3 \) is apolar to a pencil of elliptic normal sextic curves on a Veronese surface.

**Proof.** Indeed, by Lemma 3.21, the \((35 \times 21)\)-matrix \( M_2 \) has rank at most 20 along the determinantal hypersurface \( V_{10}(F) = Y_F \). Since it has rank 20 at some point, it must have rank 20 at a general point of \( V_{10}(F) \), while \( V_{10}(F) \) is singular where the rank is at most 19. The lemma therefore follows from Corollary 3.20. \[ \square \]
Remark 3.24. We have computed with Macaulay2 [18] for certain cubic forms $f$, that $V_{10}(F)$ is a hypersurface of degree 9 whose singular locus is a surface of degree 140 that coincides with the locus where $M_2$ has rank at most 19. Therefore we conjecture that this holds for a general $f$.

Lemma 3.25. Let $f$ be a cubic form of rank 9 and assume that there is a 9-tuple of points apolar to $f$ that is a divisor $D$ on an elliptic sextic curve and that $2D$ is not a cubic hypersurface divisor on the curve. Then there are exactly two subschemes of length 9 that are apolar to $f$.

Proof. Let $D = \{p_1, \ldots, p_9\}$ be a set of points on an elliptic sextic curve $E$ apolar to $f$. Then the Gale transform of the points $D$ are 9 points $D' \subset \mathbb{P}^2$. The Gale transform (cf. [11]) reembeds $E$ as a cubic curve $E'$ through the points $D'$ in $\mathbb{P}^2$, such that the lines in the plane intersect $E'$ in divisors $H_3$ equivalent to $D - H_6$, where $H_6$ is a hyperplane divisor on $E$ in $\mathbb{P}^5$. Since $2D$ is not equivalent to $3H_6$, the cubic divisor in the plane $3H_3 = 3D - 3H_6 = D + (2D - 3H_6)$ is not equivalent to $D$. Therefore $D'$ lies on a unique cubic curve in the plane, and likewise $E$ is the unique elliptic sextic curve in $\mathbb{P}^5$ through $D$. The curve $E$ is apolar to $f$, and we claim that any 9-tuple of points apolar to $f$ lies on this curve.

By Terracini’s Lemma, (cf. [21], [24]), the tangent space to the 8-th secant variety of the 3-uple embedding $W_3 \subset \mathbb{P}^{55}$ of $\mathbb{P}^5$ at the point $[f]$ is the span of the tangent spaces of any 9 points in $W_3$ whose span contains $[f]$. The tangent space to the 8-th secant variety at $[f]$ is therefore defined by the linear space of cubic hypersurfaces that are singular at $p_1, \ldots, p_9$. The curve $E$ is contained in four Veronese surfaces, corresponding to the four square roots of the hyperplane line bundle of degree 6. The secant varieties of these Veronese surfaces generate a pencil of cubic hypersurfaces singular along the elliptic curve. Their intersection is precisely the union of secant lines to $E$, so there are no other cubics singular along $E$, and $E$ is the common singular locus of this pencil.

We will show that these hypersurfaces are precisely the cubic hypersurfaces singular at $p_1, \ldots, p_9$. Since the divisor $2D$ is not linearly equivalent to a cubic hypersurface divisor, a cubic hypersurface singular in $D$ must contain the curve $E$. Furthermore, on any smooth intersection $S$ of three quadrics containing the curve, the curve $E$ has trivial normal bundle. Therefore, the residual of a cubic hypersurface section of $S$ that contains $E$, meets the curve in a divisor equivalent to a cubic section. Hence, a cubic that is singular along $D$, must contain the doubling of the curve in the three quadrics. Varying the complete intersection surface $S$, we may conclude that the cubic must be singular along the curve.

Summing up we see that tangent space of the 8-th secant variety of $W_3$ at the point $[f]$ has codimension 2 in $\mathbb{P}^{55}$ and that any 9-tuple of points on $W_3$ whose span contains $[f]$ is contained in the reembedding $E''$ of $E$ in $W_3$.

The curve $E''$ in $W_3$ is an elliptic normal curve of degree 18. By [7, Proposition 5.2], and its proof, when $2D$ is not equivalent to $3H_6$ there is unique divisor $D'$ of degree 9 on $E''$, distinct from $D$, whose span in the 3-uple embedding
Lemma 3.26. Let $F$ be a fourfold defined by a cubic form $f$, that has no partials of rank $\leq 3$ and whose apolar ideal $I_f$ has a minimal free resolution with Betti numbers

\begin{equation*}
\begin{array}{cccccccc}
1 & - & - & - & - & - & - & - \\
- & 15 & 35 & 21 & - & - & - & - \\
- & - & 21 & 35 & 15 & 1 & - & - \\
- & - & - & - & - & - & - & 1 \\
\end{array}
\end{equation*}

Assume that the $(35 \times 21)$-matrix $M_2$ of linear second order syzygies has rank 21 at a general point, and that there is a 10-tuple of points $Z \subset \mathbb{P}(V)$ apolar to $f$ and a point $[l] \in Z$ at which $M_2$ has rank 20, such that the 9 points $Z_0 = Z \setminus [l]$ form a divisor $D$ on an elliptic sextic curve $E_{Z_0}$. Assume furthermore that the divisor $2D$ is not equivalent to a cubic hypersurface divisor on $E_{Z_0}$, and that $[l]$ is not contained in the secant variety of any Veronese surface containing $E_{Z_0}$. Then the projection $I_{VSP} \to V_{10}(F)$ is generically 2 : 1.

Proof. Note that the cubic form $f$ has rank 10 and that $f - cl^3$ has rank 9 for some $c \in \mathbb{C}$. In fact, since $M_2$ has rank 20 at $[l]$, the ideal $I_f$ has a unique second order linear syzygy vanishing at $[l]$. By Lemma 3.19, this syzygy determines uniquely the curve $E_{Z_0}$. In particular, there is a unique $c$ such that $f - cl^3$ has rank 9. By Lemma 3.25, there are exactly two points in the fiber of the projection $I_{VSP} \to V_{10}(F)$ over $[l]$. Since the conditions on $Z$ are open, the lemma follows. \qed

4. The divisor of cubic fourfolds apolar to a Veronese

In the first part of this section we show (Corollary 4.5) that for a general cubic fourfold $F$ apolar to a Veronese surface $\Sigma$, i.e. in the set $D_{V_{-ap}}$, the variety $V_{10}(F)$ is singular along a $K3$ surface, and then (Corollary 4.7) that the hypersurface $V_{10}(F)$ introduced and studied in the previous section is singular along $\Sigma$. Subsequently, we show (Corollary 4.9) that the general $F$ in $D_{V_{-ap}}$ is apolar to finitely many Veronese surfaces, by exhibiting an $F$ in $D_{V_{-ap}}$ such that the singular locus of $V_{10}(F)$ cannot contain a one-dimensional family of Veronese surfaces. Next, we extend results in Section 3 to show (Corollary 4.10 and Propositions 4.11 and 4.13) that $D_{V_{-ap}}$ is a divisor different from $D_{rk3}$ and $D_{copl}$, and that the fourfold $V_{10}(F)$ does not meet the singular locus of the Hilbert scheme for a general $F$ in $D_{V_{-ap}}$ (Corollary 4.12). In the final part of the section we show (Proposition 4.16) that $D_{V_{-ap}}$ is not a Noether Lefschetz divisor in the moduli space of smooth cubic fourfolds. The Propositions 4.11 and 4.16 and Corollaries 4.9 and 4.12 are applied in Section 5 to show that for a general $[f] \in D_{V_{-ap}}$, the fourfold $V_{10}(F)$ is smooth outside a surface along which it has quadratic singularities.

By a direct calculation in an example we now prove:
Proposition 4.1. Let $F$ be a general cubic fourfold apolar to a Veronese surface $\Sigma$.

(i) $F$ has cactus rank 10. Hence no length 9 subscheme of $\mathbb{P}(V)$ is apolar to $F$.

(ii) $F$ is nonsingular and the form $f$ defining $F$ has no partial derivatives of rank $\leq 3$.

(iii) The minimal free resolution of the apolar ideal $I_f$ has Betti numbers

\[
\begin{array}{cccccccc}
1 & - & - & - & - & - & - \\
- & 15 & 35 & 21 & - & - & - \\
- & - & - & 21 & 35 & 15 & - & 1 \\
- & - & - & - & - & - & 1 \\
\end{array}
\]

and the matrix $M_2$ of linear second order syzygies of $I_f$ has rank 20 at a general point of $\Sigma$.

(iv) $Y_F = V_{10}(F)$ is an irreducible fourfold singular in codimension at least 2.

Proof. We find with Macaulay2 [18] a cubic form apolar to a Veronese surface $\Sigma$, and compute the resolution of its annihilator (apolar ideal). Let $\Sigma$ be the Veronese surface defined by the $(2 \times 2)$-minors of

\[
\begin{pmatrix}
x_0 & x_1 & x_2 \\
x_1 & x_3 & x_4 \\
x_2 & x_4 & x_5 \\
\end{pmatrix}
\]

So the ideal of $\Sigma$ is generated by

\[
(x_0x_3 - x_1^2, x_0x_5 - x_2^2, x_3x_5 - x_4^2, x_0x_4 - x_1x_2, x_1x_4 - x_2x_3, x_1x_5 - x_2x_4)
\]

By differentiation one may check that each of these quadratic forms annihilates the following cubic form:

\[
f = y_0^2y_1 + y_1y_2^2 - 2y_1y_2y_3 - y_2y_3^2 - y_1^2y_4 + 2y_0y_2y_4 - 2y_0y_3y_4 - 2y_1y_3y_4 + 2y_0y_1y_5 + y_2y_3^2 + y_3y_5^2.
\]

So $f$ is apolar to the Veronese surface $\Sigma$. The apolar ideal of the cubic form $f$ has Betti numbers

\[
\begin{array}{cccccccc}
1 & - & - & - & - & - & - \\
- & 15 & 35 & 21 & - & - & - \\
- & - & - & 21 & 35 & 15 & - & 1 \\
- & - & - & - & - & - & 1 \\
\end{array}
\]

Its $35 \times 21$-matrix $M_2$ of second order linear syzygies restricted to the plane

\[x_0 = x_3 = x_4 - x_5 = 0,\]

has rank 20 along a curve of degree 9. Reduced modulo 5 the defining form for this curve is
A direct computation shows that it is nonsingular, which proves (iv). In particular the generic rank of the matrix $M_2$ is 21 for $f$. Therefore, by Lemma 3.18, the cactus rank of $f$ is 10, which proves (i).

A direct computation shows that $F = V(f)$ is nonsingular, that $f$ has no partials of rank 3, and that the matrix $M_2$ for the apolar ideal of $f$ has rank 20 at the point $V(x_0, x_1, x_2, x_3, x_4) \in \Sigma$, hence at a general point on $\Sigma$, which proves (ii) and (iii), respectively. \hfill \Box

Let $W$ be a vector space of rank 3, and $V = S^2W$, and recall the linear map (cf. (2))

$$s : S^6W \to S^3V \quad \text{s.t. } s(a^6) = (a^2)^3$$

For $g \in S^6W$, we consider the cubic form $f = s(g) \in S^3V$. Let $C = V(g) \subset P(W^*)$ and $F = V(f) \subset P(V^*)$. Formula (18) shows that there is a natural embedding

$$\phi : VSP(C, 10) \to VSP(F, 10).$$

Indeed, if $g = \sum a_i^6$, then $f = s(g) = \sum (a_i^2)^3$. For distinct $[a_i] \in P(W)$, the morphism $\phi$ sends the length 10 subscheme $\{[a_i]|i = 1, \ldots, 10\}$ to the length 10 subscheme $\{[a_i^2]|i = 1, \ldots, 10\}$ of $P(V)$. More generally, $\phi$ associates to a length 10 apolar subscheme $Z$ of $g$ in $P(W)$ the length 10 apolar subscheme to $f$ in $P(V)$ which is the image of $Z$ under the Veronese embedding.

Remark 4.2. When $g$ is general sextic ternary form and $C = V(g)$, then $g$ has rank 10. Mukai showed in [19] that $VSP(C, 10)$ is a smooth $K3$ surface. We shall often use the notation $S_g := \phi(VSP(C, 10))$.

**Lemma 4.3.** If $g$ is a general sextic ternary form and $f = s(g)$, then $VSP(F, 10)$ is a fourfold and the projection $I_{VSP} \to V_{10}(F)$ is generically 2 : 1, where $F = V(f)$.

**Proof.** We may assume that $f = s(g)$ is a general cubic form apolar to a Veronese surface. By Remark 4.2, the sextic form $g$ has rank 10, and by Proposition 4.1, $f = s(g)$ has cactus rank 10, hence also rank 10, and $V_{10}(F)$ is a fourfold. We first claim that the projection $I_{VSP} \to V_{10}(F)$ is generically finite, and hence that $VSP(F, 10)$ is also a fourfold. For this let $\Sigma$ be the Veronese surface that is the image of the quadratic embedding of $P(W)$ in $P(V) = P(S^2W)$, and let $Z \subset \Sigma$ be a general 10-tuple of points on $\Sigma$ that is...
After possibly shrinking the parameterspace, we may assume that this fiber into the first factor. For general \( t \in Z \) where \( f \) has rank \( k \) and assume that \( Z \) is irreducible and flat over an open subset \( \Delta \subset C \). For \( t \in \Delta \) the fiber in \( I \) over \( t \) is \( I_{VSP} \), and the variety \( V_{10}(F_t) \subset P(V) \) is the image of the projection of this fiber into the first factor. For general \( t \) the variety \( V_{10}(F_t) \) is an integral hypersurface of degree 9 by Lemma 3.21, while the projection \( I_{VSP} \rightarrow V_{10}(F_t) \) is generically 2 : 1 by Lemma 3.26. Since \( V_{10}(F) \) is a hypersurface of degree 9, the generically finite map \( I_{VSP} \rightarrow V_{10}(F) \) is also 2 : 1.

To show that \( VSP(F, 10) \) is singular along \( S_\phi = \phi(VSP(C, 10)) \), we use the following general criterion for singularities of the variety of power sums of a hypersurface:

**Lemma 4.4.** Assume that \( k \) is the rank of a general hypersurface \( F' \) of degree \( d \) in \( P(V^*) \). Let \( F \subset P(V^*) \) be a hypersurface of degree \( d \) and rank \( k \) and assume that \( \dim VSP(F, k) = \dim VSP(F', k) \). Let \( [Z] \in \text{Hilb}_k(P(V)) \) be an apolar subscheme to \( F \) such that \( Z = \{ [l_1], \ldots, [l_k] \} \) consists of \( k \) distinct points. Then \( VSP(F, k) \) is singular at \( [Z] \), if there is a hypersurface of degree \( d \) in \( P(V) \) which is singular along \( Z \).

**Proof.** Consider the universal family

\[ VSP = \{ ([Z], [f]) | [Z] \in VSP(F, k) \} \subset \text{Hilb}_k(P(V)) \times P(S^dV). \]

The fiber of the second projection over a point \([f] \in P(S^dV)\) is \( VSP(F, k)\), where \( F = V(f)\). The fiber over a point \([Z] \in \text{Hilb}_k(P(V))\) of the first projection is a linear space, the linear span \( \langle \rho_d(Z) \rangle \) of the image \( \rho_d(Z) \) in \( P(S^dV) \) under the \( d \)-uple Veronese embedding \( \rho_d \). Now, consider a point \(( [Z], [f] ) \in VSP \) where \( Z \) is a smooth subscheme apolar to \( f \) and \( f \) has rank \( k \). Then \( Z \) belongs to the set of subschemes that impose independent conditions to polynomials of degree \( d \), which is open in the Hilbert scheme, and \( \langle \rho_d(Z) \rangle \) is a \( P^{k-1} \). Since \( \text{Hilb}_k(P(V)) \) is smooth of dimension \( kn \) near \( Z \), we conclude that \( VSP \) is smooth of dimension \( kn + k - 1 \) at \(( [Z], [f] ) \). Since \( F \) has rank \( k \),
the second projection $\text{VSP} \to \mathbb{P}(S^dV)$ is dominant. Furthermore, since the dimension of the fiber $\text{VSP}(F,k)$ of the second projection $\text{VSP} \to \mathbb{P}(S^dV)$ is equal to the dimension of a general fiber, the variety $\text{VSP}(F,k)$ is singular at a point $[Z]$ if the rank of the second projection at the point $([Z],[f])$ is less than $\dim(\mathbb{P}(S^dV))$. If $Z = ([l_1], \ldots, [l_k])$, then this rank is the dimension of the span $T_Z = \langle [l_i^{d-1}y_j] | 1 \leq i \leq k, 0 \leq j \leq n \rangle$ where $\langle y_0, \ldots, y_n \rangle = V$. In fact, from the expansion of $(l_i + y_j)^d$, we see that $l_i^{d-1}y_j$ defines a tangent direction at the point $[l_i]$, so $T_Z$ is the span of the tangent spaces to the $d$-uple embedding $\rho_d(\mathbb{P}(V))$ at the points $[l_i^d]$ (this is a special case of Terracini’s Lemma, cf. [21], [24]). Hence $\text{VSP}(F,k)$ is singular at $[Z]$ if these tangent spaces do not span $\mathbb{P}(S^dV)$.

But hyperplanes in $\mathbb{P}(S^dV)$ correspond to hypersurfaces of degree $d$ in $\mathbb{P}(V)$, and a hyperplane contains the tangent space at $[l_i^d]$ if and only if the corresponding hypersurface is singular at $[l_i]$. Therefore $\text{VSP}(F,k)$ is singular at $[Z]$ if there is a hypersurface in $\mathbb{P}(V)$ of degree $d$ singular in the points $[l_1], \ldots, [l_k]$.

\begin{corollary}
If $g$ is a general sextic ternary form and $f = s(g)$ (cf. 18), then $\text{VSP}(F,10)$ is singular along $S_g = \phi(\text{VSP}(C,10))$, where $F = V(f)$ and $C = V(g)$.
\end{corollary}

\textbf{Proof.} First, we may assume that $f = s(g)$ is a general cubic form apolar to a Veronese surface $\Sigma$. By Remark 4.2, the sextic form $g$ has rank 10, and by Proposition 4.1, $f = s(g)$ has cactus rank 10, hence also rank 10, and by Lemma 4.3, $\text{VSP}(F,10)$ is a fourfold.

Let $Z \subset \Sigma$ be a general 10-tuple of points on $\Sigma$ that is apolar to $F$. Note that $[Z] \in S_g = \phi(\text{VSP}(C,10))$. Now, since $g$ has rank 10, the points in $Z$ impose independent conditions to $S^3V^*$. According to Lemma 4.4, the variety $\text{VSP}(F,10)$ is singular at $[Z]$ if there exists a cubic fourfold singular along $Z$. This condition is satisfied in our situation since $Z$ is contained in the Veronese surface $\Sigma \subset \mathbb{P}(V)$. In fact, the Veronese surface is the singular locus of the discriminant cubic hypersurface parameterizing singular conics in $\mathbb{P}(W^*)$. \quad \Box

The next lemma is used to prove that if $F$ is a general cubic fourfold apolar to a Veronese surface $\Sigma$, then the hypersurface $V_{10}(F)$ is singular along $\Sigma$ (Corollary 4.7).

\begin{lemma}
Let $C$ be a plane curve defined by a general sextic form $g$, and let $I_{\text{VSP}} = \{([l],[Z]) | [l] \in Z \} \subset \mathbb{P}^2 \times \text{VSP}(C,10)$ be the natural incidence variety. Then the projection onto the first factor is $2 : 1$.
\end{lemma}

\textbf{Proof.} We may assume that $g$ has rank 10. Let $p = [l] \in Z \subset \mathbb{P}^2$ be a point in a general apolar subscheme of length 10. Then $Z_0 = Z - p$ has length nine and is contained in a unique smooth cubic curve $E_{Z_0}$. In fact, in the pencil $g - \lambda^9$, there is a unique form $g_1$ of rank 9: The $(10 \times 10)$-catalecticant matrix of $\mu g - \lambda^9$ has nonvanishing determinant with a zero of multiplicity 9 at $\mu = 0$,
and hence one more zero. The corank of the catalecticant matrix is the rank of the space of cubic forms apolar to $\mu g - \lambda f^6$, so the simple zero correspond to a unique sextic form $g_t$ in the pencil $g - \lambda f^6$ that is apolar to a cubic curve, i.e. apolar to the scheme $Z_0$ and the cubic curve $E_{Z_0}$. By genericity, we may assume that $2Z_0$ is not equivalent to $6H_L$ as divisors on $E_{Z_0}$, where $H_L$ is a divisor defined by a line in $\mathbb{P}^2$. We apply now Lemma 3.25 to the cubic form $s(g_t)$, and conclude that $p$ is contained in exactly two subschemes of length 10 that are apolar to $g_t$.

**Corollary 4.7.** Let $F$ be a cubic fourfold of cactus rank 10 that is apolar to a Veronese surface $\Sigma$. If the matrix $M_2$ of linear second order syzygies of the apolar ideal $I_f$ has rank 20 at a general point of $V_{10}(F)$, then this hypersurface is singular along $\Sigma$.

**Proof.** Let $F = V(f)$ and $f = s(g)$, then, by Corollary 4.5, the variety $VSP(F, 10)$ is singular along the K3 surface $S_g = \phi(VSP(C, 10))$, where $C = V(g)$, and $V_{10}(F) \subset P(V)$ is a hypersurface of degree 9, by Lemma 3.21. Now, assume that $\{g_t\}_{t \in C}$ is a general one parameter family of ternary sextic forms such that $g = g_0$. Let $g_t$ be a general member of the family. Then, by Proposition 4.1 and Remark 4.2, the sextic form $g_t$ and the cubic form $f_t = s(g_t)$ both have rank 10. Any length 9 subscheme of a general apolar scheme of length 10 of $g_t$ is contained in an elliptic normal sextic curve $E$ on $\Sigma$, and as a divisor on $E$ satisfies the condition of Lemma 3.25. The projection $I_{VSP} \to VSP(F_t, 10)$ and its restriction over $S_g$, are both finite and of degree 10.

Consider the other projection $I_{VSP} \to V_{10}(F_t)$. By Lemma 4.3, it is generically 2 : 1 and $V_{10}(F_t)$ is an irreducible hypersurface of degree 9. On the other hand, by Proposition 4.1 (iii) the Veronese surface $\Sigma$ is contained in $V_{10}(F_t)$. Let $p \in \Sigma$ be a general point. As in the proof of Corollary 4.5, if $(p, [Z]) \in I_{VSP}$, then $Z \subset \Sigma$. Therefore we may conclude, by Lemma 4.6, that the projection $I_{VSP} \to V_{10}(F_t)$ is 2 : 1 over $p$, and hence generically over $\Sigma$.

An analytic neighborhood in $VSP(F_t, 10)$ of a general point in $S_p$ is therefore isomorphic to a suitable neighborhood in $V_{10}(F_t)$ of any of the corresponding points in $\Sigma$. Therefore $V_{10}(F_t)$ is singular along $\Sigma$ if and only if $VSP(F_t, 10)$ is singular along $S_g$.

Thus, for an open neighborhood $0 \in \Delta \subset \mathcal{C}$, there is a family $\{V_{10}(F_t)\}_{t \in \Delta}$ of hypersurfaces of degree 9 whose general member is singular along $\Sigma$. To see that $V_{10}(F)$ is singular along $\Sigma$, we study this family.

Let

$$I = \{(p, [Z], t)\mid p \in Z, [Z] \in VSP(F_t, 10)\} \subset P(V) \times \text{Hilb}_{10} P(V) \times \Delta,$$

be the closure of the natural incidence, and let $VSP_\Delta(10) \subset P(V) \times \Delta$ be the image of the projection $I \to P(V) \times \Delta$. Then $I$ and $VSP_\Delta(10)$ are fivefolds, and thus the fibers of $VSP_\Delta(10) \to \Delta$ are all fourfolds. The fiber at $t \in \Delta$ therefore contains the fourfold $V_{10}(F_t)$ as a component. Since $V_{10}(F_t)$ is singular along $\Sigma$ for a general $t$, the same holds for $t = 0$ and the lemma follows. \qed
Remark 4.8. In computations we have found forms \( f \) apolar to a Veronese surface \( \Sigma \), such that \( V_{10}(F) \) is singular along the union of \( \Sigma \) and a surface of degree 140, the locus of points where the matrix \( M_2 \) of second order linear syzygies has rank at most 19. As noted in Proposition 4.1 (iii), the matrix \( M_2 \) has rank 20 generically on \( \Sigma \).

Corollary 4.9. Let \( F \) be a general cubic fourfold apolar to a Veronese surface. Then \( F \) is apolar to finitely many Veronese surfaces.

Proof. The union of a 1−dimensional family of Veronese surfaces is a threefold. So, if \( f \) is apolar to a 1−dimensional family of Veronese surfaces, then, by Lemma 3.21 and Corollary 4.7, the degree 9 determinantal hypersurface \( V_{10}(f) \) would be singular along a threefold, contradicting Proposition 4.1.

Corollary 4.10. The set \( D_{V_{ap}} \) of cubic forms that are apolar to some Veronese surface is an irreducible hypersurface in \( \mathbf{P}(S^3V) \).

Proof. The map \( g \mapsto f = s(g) \) induces a rational map

\[
\text{mod} : S^6W/\!\!/\text{Gl}(W) \to S^3V/\!\!/\text{Gl}(V).
\]

The image of \( \text{mod} \) is the locus of cubic fourfolds apolar to a Veronese surface, so \( D_{V_{ap}} \) is irreducible. That it is a divisor, follows from a dimension count: Plane sextics have \( 28 - 9 = 19 \) parameters, while cubic fourfolds have \( 56 - 36 = 20 \) parameters, so it suffices to show that \( \text{mod} \) has generically finite fiber. The fiber of \( \text{mod} \) over a point parameterizing a cubic fourfold \( F \) may be identified with the set of Veronese surfaces which are apolar to \( F \). The result thus follows from Corollary 4.9.

Proposition 4.11. A general cubic fourfold \( F \) which is apolar to a Veronese surface satisfies the conclusion of Proposition 3.1, namely, any element \( [Z] \in \text{VSP}(F, 10) \) corresponds to a length 10 subscheme \( Z \) which imposes independent conditions on cubics and is apolar to \( F \).

Proof. By Proposition 3.1, the divisorial part of the set of cubic fourfolds not satisfying this conclusion is contained in the union of the irreducible divisors \( D_{rk3} \) and \( D_{cpl} \) introduced in Section 2. As we know that the set of cubics apolar to a Veronese surface is an irreducible divisor which is different from \( D_{rk3} \) by Proposition 4.1 (ii), the result follows from the following Proposition 4.13.

Corollary 4.12. For a general cubic fourfold \( F \) which is apolar to a Veronese surface, \( \text{VSP}(F, 10) \) does not meet \( \text{Sing}(\text{Hilb}_{10}(\mathbf{P}(V))) \).

Proof. This follows from Proposition 4.1(ii) which guarantees that the form \( f \) that defines \( F \) has no partial derivative of rank \( \leq 3 \), Proposition 4.11 and Proposition 3.5.

Proposition 4.13. The divisors \( D_{cpl} \) and \( D_{V_{ap}} \) are distinct.
Proof. We shall distinguish $D_{\text{copl}}$ and $D_{V-\text{ap}}$ by proving that their intersections

$$D_{V-\text{ap}} \cap D_{IR} \quad \text{and} \quad D_{\text{copl}} \cap D_{IR}$$

with $D_{IR}$ are distinct.

Recall from Section 2 that $D_{IR}$ denotes the set of cubic fourfolds $F_{IR}(S)$ associated to a $K3$ surface section $S = P^8_S \cap G(2,6) \subset P^{14}$. The dual space $P^5_S := (P^8_S)^\perp \subset \tilde{P}^{14}$ intersects the Pfaffian cubic hypersurface, the secant variety of $\tilde{G}(2,6) \subset \tilde{P}^{14}$, in a Pfaffian cubic fourfold $F_{BD}(S)$. Furthermore, by [15, Lemma 3.9 and Proposition 3.15], there is an identification $V_{10}(F_{IR}(S)) = F_{BD}(S)$.

**Lemma 4.14.** Let $F_{BD}(S) \subset P^5_S$ be a Pfaffian cubic fourfold with no rank 2 points, i.e. $P^5_S \cap G(2,6) = \emptyset$, and let $S = P^5_S \cap G(2,6)$ be the corresponding linear section of $G(2,6)$. Then $F_{IR}(S)$ has cactus rank 10, and $S$ is birational to a component of the Hilbert scheme of rational quartic surface scrolls in $F_{BD}(S)$ that are apolar to $F_{IR}(S)$.

**Proof.** If $F_{BD}(S)$ has no rank 2 points, then $P^5_S = (P^8_S)^\perp$ defines the apolar ideal $I_f$ of a cubic fourfold $F_{IR}(S) = V(f)$, and this fourfold has cactus rank 10, (cf. [15, 3.5 and Lemma 3.6]). By [15, Lemma 2.9], each secant line to $S$ defines a pair of rational quartic surface scroll in $F_{BD}(S)$ that intersect along scheme of length 10 apolar to $F_{IR}(S)$. The two scrolls correspond to the points of intersection on the variety $S$. □

If a cubic fourfold $F$ of cactus rank 10 is apolar to a Veronese surface, then, by Corollary 4.7, $V_{10}(F)$ must contain this Veronese surface. So the proposition follows by finding a cubic fourfold $F = F_{IR}(S) \in D_{\text{copl}} \cap D_{IR}$, such that the Pfaffian cubic $F_{BD}(S)$ contains no Veronese surface.

We first consider Pfaffian cubic fourfolds that contain a plane. For a smooth cubic fourfold $F$, let $A(F) := H^4(F,\mathbb{Z}) \cap H^{2,2}(F)$, the lattice of integral middle Hodge classes.

**Lemma 4.15.** If $F$ is a general smooth Pfaffian cubic fourfold that contains a plane $P$ intersecting a rational quartic surface $S_4$ in $F$ along a conic section, then $A(F)$ does not contain the class of a Veronese surface. Furthermore the Pfaffian cubic fourfolds that contain such a plane form a divisor in the variety of Pfaffian cubic fourfolds.

**Proof.** We may assume that $A(F)$ has rank 3, generated by the classes of $h^2, [S_4]$ and $[P]$ (cf. [6, Example 3.1 and Theorem 3]). The intersection matrix is

$$
\begin{pmatrix}
h^2 & [S_4] & [P] \\
h^2 & 3 & 4 & 1 \\
[S_4] & 4 & 10 & 0 \\
[P] & 1 & 0 & 3 
\end{pmatrix}
$$

The class of a Veronese surface $\Sigma$ in $F$ would have intersections

$$h^2 \cdot [\Sigma] = 4, [\Sigma]^2 = 12$$
We now exhibit a cubic form \( f \) last statement, see [1, Section 2]. again means that 8 must divide the right hand side, a contradiction. For the intersection numbers we get
\[ 3[\Sigma]^2 - ([\Sigma] \cdot [h^2])^2 = 14b^2 + 8c^2 - 8bc = 20. \]
Since 4 divides the right hand side, \( b \) in the left hand side must be even, which means that 8 must divide the right hand side, a contradiction. For the last statement, see [1, Section 2].

We now exhibit a cubic form \( f \) in \( D_{copol} \) that is apolar to a rational quartic surface scroll and has both rank and cactus rank 10. By Lemma 2.4, it belongs to \( D_{copol} \cap D_{IR} \).

The cubic form
\[
\begin{align*}
f &= -7x_0^3 + 9x_0^2x_1 - 12x_0x_1^2 + x_1^3 - 12x_0^2x_2 + 6x_0x_1x_2 + 3x_0^2x_3 \\
&\quad - 3x_1^2x_3 - 6x_0x_2x_3 - 6x_1x_2x_3 + 3x_0^2x_2^3 - 3x_2^2x_3^3 + x_3^4 - 6x_0x_1x_4 - 3x_1^2x_4 \\
&\quad - 6x_0x_2x_4 - 6x_1x_3x_4 - 3x_0x_2^2 - 3x_0^2x_2x_5 - 6x_0x_1x_5 + 6x_2^2x_5 \\
&\quad - 6x_0x_3x_5 + 6x_2x_4x_5 + 3x_1x_5^2 - x_5^3
\end{align*}
\]
is apolar to the two quartic surface scrolls \( S_4 \) and \( S'_4 \) defined by the 2-minors of
\[
\begin{pmatrix}
x_0 & x_1 & x_3 & x_4 \\
x_1 & x_2 & x_4 & x_5
\end{pmatrix}
\quad \text{and} \quad
\begin{pmatrix}
x_3 & x_4 & x_0 + x_1 + x_5 & x_1 - x_2 + x_4 \\
x_4 & x_5 & x_1 - x_3 + x_4 & x_0 + x_2 - x_3
\end{pmatrix}
\]
respectively, so \( f \) belongs to \( D_{IR} \). The intersection \( S_4 \cap S'_4 \) of the two scrolls is the union of the six points \( Z_6 \) defined by the 2-minors of
\[
\begin{pmatrix}
x_0 & x_1 & x_3 & x_4 & x_0 + x_1 + x_5 & x_1 - x_2 + x_4 \\
x_1 & x_2 & x_4 & x_5 & x_1 - x_3 + x_4 & x_0 + x_2 - x_3
\end{pmatrix}
\]
and the four points
\[
V(x_0x_2 - x_1^2, x_0^2 + x_0x_1 + 2x_1x_2, x_3, x_4, x_5)
\]
in the plane \( V(x_3, x_4, x_5) \), so \( f \) belongs also to \( D_{copol} \) and has rank at most 10. The resolution of the apolar ideal \( I_f \) has Betti numbers
\[
\begin{array}{cccccccc}
1 & - & - & - & - & - \\
- & 15 & 35 & 21 & - & - \\
- & - & 21 & 35 & 15 & - \\
- & - & - & - & - & 1
\end{array}
\]
and the matrix \( 35 \times 21 \)-matrix \( M_2 \) of second order linear syzygies of \( I_f \) has no syzygies. So we conclude that \( f \) has cactus rank 10 by Lemma 3.18 and hence also rank 10. Let \( F = V(f) \). Then \( F = F_{IR}(S) \) for some \( K3 \) surface \( S \), and \( F_{BD}(S) \) is the corresponding Pfaffian cubic that contains the two quartic scrolls \( S_4 \) and \( S'_4 \). Since each scroll intersects the plane \( P = V(x_3, x_4, x_5) \) in a conic section, the plane \( P \) is contained in \( F_{BD}(S) \) and \( A(F_{BD}(S)) \) contains the rank three lattice generated by \( h^2, [S_4] \) and \( [P] \) with intersection matrix as

\begin{align*}
\begin{pmatrix}
1 & - & - & - & - & - \\
- & 15 & 35 & 21 & - & - \\
- & - & 21 & 35 & 15 & - \\
- & - & - & - & - & 1
\end{pmatrix}
\end{align*}
in the proof of Lemma 4.15. By Lemma 4.15, the Pfaffian cubic fourfolds \( F \) that contain a plane that intersect a quartic scroll in a conic form a family of codimension one in the divisor of Pfaffian cubic fourfolds. But \( D_{IR} \cap D_{copl} \) is a divisor in \( D_{IR} \), so the corresponding set of Pfaffian cubics also has codimension one in the divisor of Pfaffian cubic fourfolds. Therefore the Pfaffians cubic fourfold \( F_{BD}(S) \) corresponding to a general cubic fourfold \( F_{IR}(S) \in D_{IR} \cap D_{copl} \) is general in the sense of Lemma 4.15, and does not contain the class of a Veronese surface.

This concludes the proof of Proposition 4.13. □

We conclude this section with the following result concerning the divisor \( D_{V-ap} \).

Proposition 4.16. The divisor \( D_{V-ap} \) is not a Noether-Lefschetz divisor.

Here by a Noether-Lefschetz divisor (or component of the Hodge loci, see [22]), we mean a divisor \( D \) along which a locally constant nonzero primitive rational cohomology class in \( H^4(F_b, \mathbb{Q}) \), \( b \in D \), remains a Hodge class. Equivalently, as the Hodge conjecture is satisfied by cubic fourfolds, the cubic fourfolds \( F_b \) parameterized by such a divisor carry a codimension 2 cycle whose cohomology class is not proportional to the class \( h^2, h = c_1(O_{F_b}(1)) \). Hodge theory shows that in the case of cubic fourfolds, the Hodge loci are hypersurfaces in the moduli space, as a consequence of the equality \( h^{3,1}(F) = 1 \) (see [22]).

Proof of Proposition 4.16. First of all, we recall that in the moduli stack \( \mathcal{M} \) of smooth cubic fourfolds (or in the local universal family of deformations), Noether-Lefschetz divisors have a smooth normalization. More precisely, each local branch \( \mathcal{M}_\alpha \) near a cubic fourfold \( [F] \) is defined by a class \( \alpha \in H^4(F_b, \mathbb{Q}) \) where \( \mathcal{M}_\alpha \) is the “locus of points \( t \in \mathcal{M} \) where the class \( \alpha_t \in H^4(F_t, \mathbb{Q}) \) deduced from \( \alpha \) by parallel transport is a Hodge class”, and the statement is that \( \mathcal{M}_\alpha \) is smooth. We refer to [22] for various local descriptions of these Hodge loci and their local study. The smoothness follows from [22, Corollary 3.3], and from the following fact:

Lemma 4.17. Let \( F \) be a nonsingular cubic fourfold, and \( 0 \neq \alpha \in H^2(F, \Omega^2_F)_\text{prim} \). Then the cup-product-contraction map

\[
\circ \alpha : H^1(F, T_F) \to H^3(F, \Omega^3_F)
\]

is surjective.

This lemma can be proved directly using Griffiths’ description of the infinitesimal variations of Hodge structures of hypersurfaces, or by using the Beauville-Donagi isomorphism between the variation of Hodge structures on \( H^4(F, \mathbb{Q})_{\text{prim}} \) and the variation of Hodge structures on \( H^2(L(F), \mathbb{Q})_{\text{prim}} \), where \( L(F) \) is the Fano variety of lines of \( F \), together with general properties of the period map for hyper-Kähler manifolds.

The universal family of deformations of the cubic Fermat hypersurface \( F_{Fermat} = V(f_{Fermat}) \in \mathbb{P}^5 \) can be obtained as follows: in \( S^3V \) we choose a
linear subspace $T$ which is transverse to the tangent space at the point $f_{\text{Fermat}}$ to the orbit of $f_{\text{Fermat}}$ under $\text{Gl}(V)$, and we restrict the universal hypersurface in $S^3V \times \mathbb{P}^5$ to $T \times \mathbb{P}^5$, where $T$ is embedded in an affine way in $S^3V$, by $t \mapsto f_{\text{Fermat}} + t$. Since the differential at $(\text{Id}, 0)$ of the map

$$\text{Gl}(V) \times T \rightarrow S^3V,$$

$$(\gamma, t) \mapsto \gamma(f_{\text{Fermat}} + t),$$

is an isomorphism, it is a local isomorphism in the analytic topology, hence there is a neighborhood $U$ of $f_{\text{Fermat}}$ in $S^3V$ and a holomorphic retraction $\pi : U' \rightarrow U \subset T$ with the property that $\pi(g)$ is the unique point of intersection of $U' \cap O_g$ with $T$ (where $O_g$ is the orbit of $g \in U$ under $\text{Gl}(V)$). It is well-known (see [23, Remark 6.16]) that the tangent space to the orbit of $f_{\text{Fermat}}$ at $f_{\text{Fermat}}$ is the degree 3 part of the Jacobian ideal of $f_{\text{Fermat}}$, generated by the partial derivatives of $f_{\text{Fermat}}$. If we write $f_{\text{Fermat}} = \sum_{i=0}^5 X_i^3$, the Jacobian ideal $f_{\text{Fermat}}$ is generated by the $X_i^2$, so there is a natural such complementary subspace $T$; the vector subspace of $S^3V$ generated by the $X_i X_j X_k$ for $i, j, k$ all distinct.

As the map $s_{\text{mod}} : S^6W/\text{Gl}(W) \rightarrow S^3V/\text{Gl}(V)$ is induced by the linear map $s : S^6W \rightarrow S^3V$, the divisor $D_{V-\text{ap}} \subset S^3V/\text{Gl}(V)$ comes from a divisor $D_U$ in $U \subset T \subset S^3V$ (if $U$ is a analytic open set which will be the basis of a universal family of deformations of $F_{\text{Fermat}}$), where $D_U$ is obtained as the image of the composition of the linear map $s : S^6W \rightarrow S^3V$ with $\pi : U' \rightarrow U \subset T$, where it is defined.

The following proposition implies that $D_{V-\text{ap}}$ is not a Noether-Lefschetz divisor, thus concluding the proof of the proposition.

**Proposition 4.18.** The local branches of the divisor $D_U$ at the origin are singular.

**Remark 4.19.** We cannot identify here $D_U$ with an open set of $D_{V-\text{ap}}$. Indeed, $D_U$ is a divisor in the universal family of deformations of $F_{\text{Fermat}}$, and its image $D_{V-\text{ap}}$ in $S^3V/\text{Gl}(V)$ is obtained by taking the quotient of $D_U$ by the group of automorphisms of $F_{\text{Fermat}}$, which is nontrivial. If $D_{V-\text{ap}}$ is a Noether-Lefschetz divisor, then the divisor $D_U$ in the universal family of deformations must have smooth local branches. The criterion, that a Noether-Lefschetz divisor has smooth local branches can be applied only in the universal family of deformations, which is itself smooth.

**Proof of Proposition 4.18.** We wish to exploit the following observation:

**Lemma 4.20.** For a generic sextic polynomial $g \in S^6W$ which is the sum of six 6-th powers of elements of $W$, $f = s(g)$ is (conjugate to) the Fermat polynomial $g_F = \sum_{i=0}^5 X_i^3$.

**Proof.** This follows immediately from formula (2), which says that if $g = \sum_{i=0}^5 a_i^6$ then $f = \sum_{i=0}^5 (a_i^2)^3$. On the other hand, for a generic choice of the $a_i$’s, the $a_i^2$ provide a basis $X_i, i = 0, \ldots, 5$ of $V = S^2W$. □
We fix $a_0, \ldots, a_5$ providing a basis $X_i = a_i^2, i = 0, \ldots, 5$ of $V$. For any $b_\bullet = (b_0, \ldots, b_5) \in W^6$ and $b \in W$, we consider the curve in $S^6W$ parameterized by the coordinate $t$, of the form

$$t \mapsto g_{b_\bullet, b, t} := \sum_{i=0}^{6} b_i^6 + tb^6 \in S^6W.$$ 

At $t = 0$, the corresponding curve $t \mapsto s(g_{b_\bullet, b, t}) \in S^3V$ passes through $s(\sum_{i=0}^{6} b_i^6)$, which is equal to $\sum_{i=0}^{5} (b_i^2) \in S^3V$. The later polynomial is not equal for generic $b_\bullet$ to the Fermat polynomial $f_{Fermat} = \sum_i X_i^2$ but it is canonically conjugate to it, namely, let $\gamma_\bullet \in GL(V)$ be determined by

$$\gamma_\bullet(b_i^2) = X_i, \ i = 0, \ldots, 5.$$ 

Then we have

$$\gamma_\bullet(s(\sum_{i=0}^{6} b_i^6)) = f_{Fermat},$$

and may conclude that the curve

$$t \mapsto f_{b_\bullet, b, t} := \gamma_\bullet(s(g_{b_\bullet, b, t})) \in S^3V, \ t \in \mathbb{C}$$

passes through $f_{Fermat}$ at $t = 0$. By definition, its image in $S^3V/GL(V)$ is contained in $\text{Im} s_{mod}$. Furthermore, for small $t$, $f_{b_\bullet, b, t}$ belongs to the small open set where the holomorphic retraction $\pi : U \to T$ is defined, so that $\pi(f_{b_\bullet, b, t}) \in D_U$ for any such $(b_\bullet, t)$. Thus there must be one branch $D'_U$ of $D_U$ such that $\pi(f_{b_\bullet, b, t}) \in D'_U$ for any $(b_\bullet, t)$, since the parameter space for the family $f_{b_\bullet, b, t}$ is smooth hence in particular normal. Let us now prove that $D'_U$ is not smooth at the point $f_{Fermat}$. The derivative at 0 with respect to $t$ of the holomorphic map

$$t \mapsto \pi(f_{b_\bullet, t}) \in T$$

is obtained by applying the projection

$$p : S^3V \to T \cong S^3V/J_{f_{Fermat}}$$

to $\gamma_\bullet(s(b_i^6)) = \gamma_\bullet((b_i^2)^3)$. The above reasoning shows that all these elements lie in the Zariski tangent space $T_{D'_U, 0}$ at the point 0 (parameterizing the Fermat equation). The proof that $D'_U$ is not smooth is thus concluded with the following lemma:

**Lemma 4.21.** The set $S$ of elements $p(\gamma_\bullet((b_i^2)^3)) \in T$ generates $T$ as a vector space.

**Proof.** Choose two independent elements $Y_0, Y_1$ of $W$. Then the three elements $Y_0^2, Y_1^2, (Y_0 + Y_1)^2$ are independent in $S^2W$. For a generic choice of $a_3, a_4, a_5 \in W$, the set

$$Y_0^2, Y_1^2, (Y_0 + Y_1)^2, a_3^2, a_4^2, a_5^2$$

forms a basis of $V$. We choose

$$b_\bullet = (Y_0, Y_1, Y_0 + Y_1, a_3, a_4, a_5).$$
Then

\begin{equation}
\gamma_b(Y_0^2) = X_0, \gamma_b(Y_1^2) = X_1,
\end{equation}

\begin{equation}
\gamma_b((Y_0 + Y_1)^2) = X_2, \gamma_b(a_i^2) = X_i, i = 3, 4, 5.
\end{equation}

Choose now for \(b\) a generic linear combination of \(Y_0\) and \(Y_1\). Then we can write

\(b^2 = \alpha Y_0^2 + \beta Y_1^2 + \gamma (Y_0 + Y_1)^2\), with the coefficients \(\alpha, \beta, \gamma\) all nonzero. It follows that

\((b^2)^3 = 6\alpha\beta\gamma(Y_0)^2(Y_1)^2(Y_0 + Y_1)^2 + P(Y_0)^2, (Y_1)^2, (Y_0 + Y_1)^2)\)

where the cubic polynomial \(P\) contains all monomials in \((Y_0)^2, (Y_1)^2, (Y_2)^2\) containing at least one quadratic power of one of the variables. Applying the transformation \(\gamma_b\) of (19) and the projection \(p\), we get

\[p(\gamma_b((b^2)^3)) = 6\alpha\beta\gamma X_0 X_1 X_2\]

since all the monomials in the \(X_j\) containing at least a quadratic power of the variables are in \(J^1_{\text{f,formal}}\). We thus proved that the set \(S\) contains \(X_0X_1X_2\), and the same proof would show that \(S\) contains \(X_i X_j X_k\) for arbitrary distinct indices \(i, j, k\). Thus \(S\) generates \(T\) as a vector space.

\(\Box\)

The proof of Proposition 4.18 is finished.

\(\Box\)

5. Local structure of \(VSP\) for a cubic fourfold apolar to a Veronese surface

Let \(W\) be a 3-dimensional vector space, and let \(g \in S^6 W, f = s(g) \in S^3(S^2 W)\) be as in the previous section, i.e. \(C = V(g)\) is a plane sextic curve, and \(F = V(f)\) is a cubic fourfold. Our goal in this section is to prove the following theorem (from which Theorem 1.8 of the introduction immediately follows):

**Theorem 5.1.** Assume that \(g\) is a general ternary sextic form, and let \(f = s(g)\).

(i) The variety \(VSP(F, 10)\) is smooth of dimension 4 away from the K3 surface \(S_g = VSP(C, 10)\). In particular, there is only one Veronese surface apolar to \(f\), so we may denote by \(S_f\) the surface \(S_g\).

(ii) The singularities of \(VSP(F, 10)\) are quadratic nondegenerate in the normal direction to \(S_f\) at any point of \(S_f\).

**Proof of Theorem 5.1.** (i). We know, by Corollary 4.10, that the set of cubics apolar to a Veronese surface is a divisor \(D_{V-ap}\) in the space parameterizing all cubics. Let

\begin{equation}
VSP_{V-ap} := \{(Z_1, [f]) \in \operatorname{Hilb}_{10}(\mathbb{P}^5) \times D_{V-ap}, I_Z(3) \subset H_f\}
\end{equation}

be the universal family of \(VSP\)'s of cubics apolar to a Veronese surface, with projection

\[pr_2 : VSP_{V-ap} \to \mathbb{P}(S^3 V)\]

We consider the dense open \(D^0_{V-ap} \subset D_{V-ap}\) defined as the set of points \([f]\) in the smooth locus of \(D_{V-ap}\) such that \(f = s(g)\) for a ternary sextic form \(g\) of

\textbf{Documenta Mathematica 22 (2017) 443–492}
rank 10 for which $S_g$ is integral, and Corollary 4.12 and Propositions 4.11 and 4.1, (i) are satisfied.

We prove the following:

**Lemma 5.2.** Let $[f] \in D_{V-\text{ap}}^0$. Then there is only one Veronese surface that is apolar to $f$, thus determining a unique curve $C$ defined by a ternary sextic form $g$ such that $S_g = VSP(C, 10) \subset VSP(F, 10)$. In this case we denote by $S_f$ this surface $S_g$.

Furthermore, denoting by $VSP_{V-\text{ap}, 0}$ the restriction to $D_{V-\text{ap}}^0$ of the family $VSP_{V-\text{ap}}$, $VSP_{V-\text{ap}, 0}$ is nonsingular away from the family $S \subset VSP_{V-\text{ap}, 0}$ of surfaces $S_f$.

**Proof.** We identify $f$, as before, with a hyperplane $H_f$ in $S^3V^*$. Let $K \subset \text{Hom}(H_f, S^3V^*/H_f) = T_{(S^3V), f}$ be the tangent space of $D_{V-\text{ap}}$ at $[f]$, with $f = s(g)$ for some $g \in H^0(\mathbb{P}^2, \mathcal{O}_{\mathbb{P}^2}(6))$ and some Veronese embedding $\Sigma \subset \mathbb{P}(V)$ of $\mathbb{P}^2$. We denote again by $h \in S^3V^*$ the discriminant cubic form, such that $V(h)$ is singular along $\Sigma$. Notice that $h \in H_f$, since $f$ is apolar to $\Sigma$.

First of all, we claim that $K^\perp$ is generated by $h$. As $K$ is a hyperplane, it suffices to show that $h$ belongs to $K^\perp$, i.e. that $\gamma(h) = 0$ for every $\gamma \in K$.

Let $[Z]$ be a general point in $S_g \subset VSP(F, 10)$. Then $Z$ is contained in a unique Veronese surface $\Sigma$ apolar to $f = s(g)$, and $VSP_{V-\text{ap}}$ contains a family $S_U = \{[Z'], [f']\} \in U | [Z'] \in S_g' \subset VSP(F', 10)$.

of surfaces in a neighborhood $U$ of the point $([Z], [f])$. Since $S_g$ is integral, we may assume that $S_U$ is smooth at $([Z], [f])$. On the other hand, the image $pr_2(S_U) \subset \mathbb{P}(S^3V)$ is dense in $D_{V-\text{ap}}$. Now, let $T_{VSP_{V-\text{ap}}, ([Z], [f])}$ be the Zariski tangent space to $VSP_{V-\text{ap}}$ at $([Z], [f])$. It contains the tangent space $T_{S_U}.([Z], [f]),$ so since $pr_2(S_U)$ is dense in $D_{V-\text{ap}}$, the tangent space $K$ to $D_{V-\text{ap}}$ at $[f]$ is the image of the linear map $pr_{2*} : T_{VSP_{V-\text{ap}}, ([Z], [f])} \to T_{(S^3V), f}$.

So to prove the claim it suffices to prove that the discriminant cubic form $h$ belongs to the orthogonal of \[ \text{Im}(pr_{2*} : T_{VSP_{V-\text{ap}}, ([Z], [f])} \to T_{(S^3V), f}). \]

Since $g$ has rank 10, we may assume that the scheme $Z$ consists of ten distinct points that impose independent conditions on cubics, so we can identify $T_{\text{Hilb}_0(V)}([Z])$ with $H^0(T_{p_{|Z}})$, and furthermore $H^0(T_{p_{|Z}})$ with $\text{Hom}_{\mathcal{O}_{\mathcal{O}_Z}}(I_Z, \mathcal{O}_Z).$ We have then the following description of the tangent space of $VSP$ at $([Z], [f])$: \( (21) \ T_{([Z], [f])} := \{ (u, \gamma) \in \text{Hom}_{\mathcal{O}_Z} (I_Z, \mathcal{O}_Z) \times \text{Hom}(H_f, S^3V^*/H_f), \gamma|_{I_Z(3)} = p \circ d_u : I_Z(3) \to S^3V^*/H_f \}, \)
where \( d_u : I_Z(3) \rightarrow H^0(\mathcal{O}_Z(3)) \) is the map induced by \( u \in \text{Hom}_{\mathcal{O}_{P^4}}(\mathcal{I}_Z, \mathcal{O}_Z) \) on global sections, and \( p : H^0(\mathcal{O}_Z(3)) \rightarrow S^3V^*/H_f \) is deduced from the quotient map \( S^3V^* \rightarrow S^3V^*/H_f \), using the fact that the restriction map \( S^3V^* \rightarrow H^0(\mathcal{O}_Z(3)) \) is surjective and that its kernel \( I_Z(3) \) is contained in \( H_f \). We just have to prove that for \( \gamma \) satisfying the equation (21), we have

\[
\gamma(h) = 0.
\]

But as \( h \in I_Z(3) \), we get \( \gamma(h) = d_u(h) \) modulo \( H_f \), and since \( h \) is singular along \( Z \), \( d_u(h) = 0 \), which proves (22). The claim is thus proved.

Note that the claim proves in particular that for \( [f] \in D_{V\rightarrow ap}^0 \), there is a unique Veronese surface apolar to \( f \) since it says that the cubic \( h \) is determined by \( K = T_{D_{V\rightarrow ap}^0}([f]) \) and on the other hand it determines \( \Sigma \), because \( \Sigma \) is the singular locus of \( V(h) \).

The proof of the smoothness of \( V_{SPV_{\rightarrow ap}\mathcal{O}} \) away from \( S \) will now use the fact that the discriminant cubic with equation \( h \) is smooth away from \( \Sigma \). The argument goes as follows: Let \( [f] \in D_{V\rightarrow ap}^0 \), \([Z] \in VSP(F,10)\), \([Z] \notin S_f \) and \( K = T_{D_{V\rightarrow ap}^0}([f]) \). Recall that the conclusion of Corollary 4.12 holds, so that \([Z] \) is a smooth point of \( \text{Hilb}_{10}(\mathcal{P}(V)) \). Furthermore, Proposition 4.11 also holds, so \( Z \) is apolar to \( f \) and imposes independent conditions on cubics. Hence \( I_Z(3) \subset H_f \), and this property gives us the local equations for \( VSP(F,10) \) inside \( \text{Hilb}_{10}(\mathcal{P}(V))_{reg} \). Differentiating these equations, the Zariski tangent space to \( VSPV_{\rightarrow ap} \) at \((\[Z],[f]\)) is thus given as before by

\[
T_{VSPV_{\rightarrow ap},([Z],[f])} := \{(u, \alpha) \in \text{Hom}_{\mathcal{O}_{P^4}}(\mathcal{I}_Z, \mathcal{O}_Z) \times K, \alpha|_{I_Z(3)} = p \circ d_u : I_Z(3) \rightarrow S^3V^*/H_f \},
\]

where \( K \) is the hyperplane in \( \text{Hom}(H_f, S^3V^*/H_f) \) of linear forms vanishing on \( h \). The variety \( VSPV_{\rightarrow ap} \) is smooth at \((\[Z],[f]\)) if the restriction map

\[
\rho_K : K \rightarrow \text{Hom}(I_Z(3), S^3V^*/H_f)
\]

is surjective, since this implies that the linear equations in (23) defining the Zariski tangent space to \( VSPV_{\rightarrow ap} \) at \((\[Z],[f]\)) are nothing but the differentials of the equations defining \( VSPV_{\rightarrow ap} \) are linearly independent.

1) If \( h \) does not vanish identically on \( Z \), then the hyperplane

\[
K \subset \text{Hom}(H_f, S^3V^*/H_f)
\]

does not contain the kernel of the surjective map

\[
\text{Hom}(H_f, S^3V^*/H_f) \rightarrow \text{Hom}(I_Z(3), S^3V^*/H_f)
\]

so the restriction map \( \rho_K \) is surjective.

2) If \( h \) vanishes on \( Z \), the image of the map \( K \rightarrow \text{Hom}(I_Z(3), S^3V^*/H_f) \) is the set of linear forms on \( I_Z(3) \) vanishing on \( h \in I_Z(3) \). Therefore, the linear equations in (23), parameterized by \( \text{Hom}_{\mathcal{O}_{P^4}}(\mathcal{I}_Z, \mathcal{O}_Z) \), are linearly dependent only if the map

\[
\text{Hom}_{\mathcal{O}_{P^4}}(\mathcal{I}_Z, \mathcal{O}_Z) \rightarrow \mathcal{C}, \quad u \mapsto d_u(h) \text{ mod } H_f
\]
is the zero map. But the map

\[ u \mapsto d_u(h) \in H^0(\mathcal{O}_Z(3)) \]

is \( H^0(\mathcal{O}_Z) \)-linear. So if its image is contained in \( H_f/I_Z(3) \), it provides a sub-
\( H^0(\mathcal{O}_Z) \)-module of \( H^0(\mathcal{O}_Z(3)) \) which is the ideal of a subscheme of \( Z \) apolar
to \( f \). By Proposition 4.1, (i), this implies that this ideal is equal to 0, that is,
the map (24) is 0.

In conclusion, if \( VSP_{V-\text{ap}} \) is singular at \([Z, f]\), then \( Z \) is contained in
the singular locus of \( h \), hence in \( \Sigma \). In other words, \([Z]\) belongs to \( S_f \).

Lemma 5.2 implies (i) by a Sard type argument and this concludes the proof
of Theorem 5.1, (i).

\[ \square \]

Proof of Theorem 5.1, (ii). We first prove the following result:

**Lemma 5.3.** For general \( g \) and \( f = s(g) \), the embedding dimension of
\( VSP(F, 10) \) is 5 at any point of \( S_f \).

**Proof.** We know that the universal family \( VSP \) is smooth and that the hyper-
surface \( VSP_{V-\text{ap}} \) contains the family of surfaces \( S \) which has generically smooth
fibers. If \( S_f \) is smooth, the corank of the map \( pr_{2*} : T_{VSP([Z],[f])} \rightarrow T_{P(S^3V)}[f] \)
is 1 everywhere along \( S_f \). This implies that the embedding dimension of
\( VSP(F, 10) \) is 5 at any point of \( S_f \).

This lemma shows that for general \( g \) and \( f = s(g) \), the variety \( VSP(F, 10) \) has
locally hypersurface singularities along \( S_f \), and our goal now is to show that
the Hessian of the local defining equation, which is a homogeneous quadratic
polynomial on the normal bundle \( N_{S_f} \), is everywhere nondegenerate. Here the
bundle \( N_{S_f} \) is defined as the quotient of \( T_{VSP(F, 10)}|_{S_f} \) by its subbundle \( T_{S_f} \).
The bundle \( N_{S_f} \) is thus locally free of rank 3 by Lemma 5.3.

We first have the following:

**Lemma 5.4.** The determinant of \( N_{S_f} \) is trivial.

**Proof.** We recall that by Proposition 4.11, \( VSP(F, 10) \) is defined as the following set:

\[ VSP(F, 10) = \{ [Z] \in \text{Hilb}_{10}(\mathbb{P}(V)), I_Z(3) \subset H_f \} \tag{25} \]

The variety \( VSP(F, 10) \) is contained in the smooth part of \( \text{Hilb}_{10}(\mathbb{P}(V)) \) and
defined according to (25) as the 0-locus of a section \( \sigma \) of the bundle \( \mathcal{F} \) with
fiber \( I_f(3)^* \) over the point \([Z] \in \text{Hilb}_{10}(\mathbb{P}(V)) \). More precisely, since we assumed
that \([f] \in D_{V-\text{ap}}^\text{Vap} \), the conclusion of Proposition 4.11 holds and thus
\( VSP(F, 10) \) is contained in the open set of \( \text{Hilb}_{10}(\mathbb{P}(V)) \) where \( \mathcal{F} \) is locally
free. In particular, \( VSP \rightarrow \mathbb{P}(S^3V) \) is flat over a neighborhood of \([f] \). For a
general \( f \in S^3V \), we know by [15] that \( VSP(F, 10) \) is a smooth Hyper-Kähler
manifold, hence in particular has trivial canonical bundle. This means that the line bundle
\[ \det(T_{\text{Hilb}_{10}(P^3)|VSP(F,10)}) \otimes (\det F)^{-1} \]
has trivial restriction to \( VSP(F,10) \), which implies that it has trivial restriction to \( VSP(F,10) \) when \( f \) is a general cubic apolar to a Veronese surface, since \( VSP \rightarrow P(S^3V) \) is flat at \([f]\).
On the other hand, the proof of Lemma 5.3 shows that the cokernel of the differential \( d\sigma \) along \( S_f \) is the trivial line bundle with fiber \( \text{Hom}(Ch, S^3V^* / H_f) \) at any point \([Z]\) of \( S_f \).
The exact sequence
\[ 0 \rightarrow T_{VSP(F,10)|S_f} \rightarrow T_{\text{Hilb}_{10}(P^3)|S_f} \rightarrow \mathcal{F}|S_f \rightarrow \text{Coker } d\sigma \rightarrow 0 \]
thus implies the triviality of \( \det T_{VSP(F,10)|S_f} \), hence the triviality of \( \det N_{S_f} \) since \( \det T_{S_f} \) is trivial. \( \square \)
Using the fact that the cokernel of the map \( d\sigma \) is the trivial line bundle on \( S_f \), we conclude that the Hessian of \( \sigma \) is a section of \( S^2N_{S_f}^* \). Here we use the following notion of Hessian for a section \( \sigma \) of a vector bundle \( E \) of rank \( r \) on a smooth variety \( Y \), at a point \( y \) where \( d\sigma \) is not of maximal rank. The Hessian is then intrinsically an element of \( (\text{Coker } d\sigma_y) \otimes S^2\Omega_{Y,y,\sigma}^* \), where \( \Omega_{Y,y,\sigma} \) is the trivial line bundle with fiber \( \text{Hom}(\text{Coker } d\sigma_y, S^2\Omega_{Y,y,\sigma}) \). (Note that \( d\sigma_y : T_{Y,y} \rightarrow E_y \) is not intrinsically defined but \( \text{Ker } d\sigma_y \) and \( \text{Coker } d\sigma_y \) are.) This Hessian is related to the usual Hessian as follows: In an adequate local trivialization of \( E \) near \( y, \sigma \) is given by a \( r \)-tuple \((\sigma_1, \ldots, \sigma_r)\) of functions on \( Y \), and we can assume that if \( k \) is the rank of \( d\sigma \) at \( y \), then \( d\sigma_1, \ldots, d\sigma_k \) are independent at the point \( y \), while \( d\sigma_{k+1}, \ldots, d\sigma_r \) vanish at \( y \). Let \( Y' \) be the smooth codimension \( k \) submanifold of \( Y \) defined by \( \sigma_i, i \leq k \). Then \( \Omega_{Y,y,\sigma} = \Omega_{Y',y}^* \) and the restriction \( \sigma|_{Y'} \) has zero differential at \( y \). Then the Hessian of \( \sigma \) at \( y \) is the \((r-k)\)-tuple of quadratic forms \((\text{Hess}(\sigma_{k+1}|_{Y'}), \ldots, \text{Hess}(\sigma_r|_{Y'}))\). If furthermore we know that the vanishing locus of \( \sigma \) has ordinary quadratic singularities along a submanifold \( Z \subset Y \), then near \( y \), we have \( Z \subset Y' \) and the Hessians \( \text{Hess}(\sigma_i|_{Y'}) \) belong to \( S^2\Omega_{Y',y} \) appearing above in fact belong to \( S^2N_{Z/Y'}^* \). In our case, \( Z \) is \( S_f \) and what we denoted by \( N_{S_f} \) is naturally isomorphic to \( N_{Z/Y'}^* \).
As the determinant of \( N_{S_f} \) is trivial, the Hessian of \( \sigma \) as a section of \( S^2N_{S_f}^* \) is a nondegenerate quadric everywhere along \( S_f \) if and only if it is nondegenerate generically along \( S_f \). The last property can be shown as follows: Recall that \( f \) is a generic cubic apolar to a Veronese surface and \([Z] \in S_f \). The pair \([Z], [f]\) can be constructed starting from a general subscheme of length 10 of the Veronese surface \( \Sigma \), and taking for \( H_f \) a general hyperplane of \( S^3V^* \) containing \( I_Z(3) \).
Take for \( Z \) a reduced subscheme consisting of ten distinct points \( x_1, \ldots, x_{10} \) in general position on \( \Sigma \). Then the hyperplane \( H_f \) is determined by a linear form \( p : S^3V^* \rightarrow S^3V^*/H_f \). This form is the composite of the projection map \( S^3V^* \rightarrow S^3V^*/I_Z(3) \) and a linear form
\[ p' : H^0(\mathcal{O}_Z(3)) \rightarrow \mathbb{C}. \]
After trivialization of $O_Z(3)$ we may write

$$ p^i = \sum_i p_i e_{v_i}, $$

for some scalars $p_i$ which can be chosen arbitrarily. Recalling that the cokernel of $d\sigma$ is generated by $\text{Hom}(\text{Ch}, S^3V^*/H_f)$, it is clear that the Hessian $\text{Hess}(\sigma)$ at the point $[Z]$ is obtained by restricting the sum $\sum_i p_i d^2 h_{x_i}$ to

$$ N_{S_p,[Z]} \subset H^0(N_{S_p}^*|Z) = \oplus_i N_{S_p}^*|x_i. $$

Here we use the same trivialization of $O_Z(3)$ as above to see the Hessian $d^2 h_{x_i}$ of $h$ at $x_i$ as an element of $S^2N_{S_p}^*|x_i$. Since $h$ has nondegenerate quadratic singularities along $\Sigma$, each of the quadrics $d^2 h_{x_i}$ is nondegenerate. We now have:

**Lemma 5.5.** The 3-dimensional vector space $N_{S_p,[Z]}$ is the orthogonal complement of the subspace $\text{Im}(H^0(\Sigma, N_{S_p}/p\Sigma))$ with respect to the quadratic form $\sum_i p_i d^2 h_{x_i}$.

**Proof.** Indeed, the space $N_{S_p,[Z]}$ is equal to the kernel of the composite map

$$ H^0(N_{S_p}^*|Z) \to \text{Hom}(I\Sigma(3), H^0(O_Z(3))) \overset{\ell_p}{\to} \text{Hom}(I\Sigma(3), S^3V^*/H_f), $$

where $H^0(N_{S_p}^*|Z) \cong \oplus_i N_{S_p}^*|x_i$ and $\ell_p' = \sum_i p_i e_{v_i}$. Let now $u \in H^0(\Sigma, N_{S_p}/p\Sigma)$, $u|Z = (u_i)$ and $v = (v_i) \in H^0(N_{S_p}^*|Z)$. Then

$$ \left(\sum_i p_i d^2 h_{x_i}\right)(u_i, v_i) = \sum_i p_i d^2 h_{x_i}(u_i, v_i). $$

The section $u \in H^0(\Sigma, N_{S_p}/p\Sigma)$ lifts to a section $U \in H^0(\mathbb{P}^5, T_{p\Sigma})$. Let $d_U : S^3V^* \to S^3V^*$ be the induced map on cubic forms. Then the degree 3 polynomial $d_U(h)$ belongs to $I\Sigma(3)$. Furthermore we have

$$ d_U(h_i, v_i) = d(d_U(h))(v_i) $$

for any $i$. It follows that

$$ \sum_i p_i d^2 h_{x_i}(u_i, v_i) = \sum_i p_i d(d_U(h))(v_i). $$

If now $(v_i)$ belongs to $N_{S_p,[Z]}$, we find that $\sum_i p_i d(d_U(h))(v_i) = 0$ and thus

$$ \sum_i p_i d^2 h_{x_i}(u_i, v_i) = 0. $$

Hence we proved that $\text{Im}(H^0(\Sigma, N_{S_p}/p\Sigma)) \to \oplus_i N_{S_p}^*|x_i)$ is perpendicular with respect to $\sum_i p_i d^2 h_{x_i}$ to the space $N_{S_p,[Z]}$. As the space $H^0(\Sigma, N_{S_p}/p\Sigma)$ is of dimension 27, the map $H^0(\Sigma, N_{S_p}/p\Sigma) \to \oplus_i N_{S_p}^*|x_i)$ is injective of maximal rank 27 for a general choice of the $x_i$’s. As the space $N_{S_p,[Z]}$ is of dimension 3, we conclude that

$$ \text{Im}(H^0(\Sigma, N_{S_p}/p\Sigma) \to \oplus_i N_{S_p}^*|x_i)) $$

**Documenta Mathematica** 22 (2017) 443–492
is the orthogonal complement with respect to $\sum_{i} p_i d^2 h_{x_i}$ of the space $N_{S_f}(V)$, since the quadratic form $\sum_{i} p_i d^2 h_{x_i}$ on the $30$-dimensional vector space $\oplus_{i} N_{S_f}/\mathbb{P}^5, x_i$ is nondegenerate.

It follows that the quadratic form $\text{Hess}(\sigma)$, that is the restriction of $\sum_{i} p_i d^2 h_{x_i}$ to $N_{S_f}(V)$, is nondegenerate if and only if the quadratic form $\sum_{i} p_i d^2 h_{x_i}$ has a nondegenerate restriction to $\text{Im}(H^0(\Sigma, N_{S_f}/\mathbb{P}^5))$. The last property may be achieved because the points $x_i$ being general, the map

$$H^0(\Sigma, N_{S_f}/\mathbb{P}^5) \rightarrow \oplus_{1 \leq i \leq 5} N_{S_f}/\mathbb{P}^5, x_i$$

is injective (hence an isomorphism). Hence any combination $\sum_{1 \leq i \leq 5} p_i d^2 h_{x_i}$ with $p_i \neq 0$ for any $i \leq 9$ has a nondegenerate restriction to $\text{Im}(H^0(\Sigma, N_{S_f}/\mathbb{P}^5)) \rightarrow \oplus_{1 \leq i \leq 5} N_{S_f}/\mathbb{P}^5, x_i$) and thus a general combination $\sum_{1 \leq i \leq 10} p_i d^2 h_{x_i}$ has a nondegenerate restriction to

$$\text{Im}(H^0(\Sigma, N_{S_f}/\mathbb{P}^5)) \rightarrow \oplus_{1 \leq i \leq 5} N_{S_f}/\mathbb{P}^5, x_i).$$

In conclusion, we proved that, for general $g$ and $f = s(g)$, at a general point $[Z] \in S_f = S_g \subset VSP(F, 10)$, the Hessian of the local defining equation of $VSP(F, 10)$ has rank $3$, and as explained above, this implies that it is everywhere nondegenerate in the normal direction to $S_f$.

6. Proof of Theorem 1.6

We first recall the statement of the result:

**Theorem 6.1.** Let $F$ be a very general cubic fourfold. Then there is no nonzero morphism of Hodge structures between $H^4(F, \mathbb{Q})_{\text{prim}}$ and $H^2(VSP(F, 10), \mathbb{Q})_{\text{prim}}$.

**Proof.** Let $B$ be the Zariski open set of $H^0(\mathbb{P}^5, \mathcal{O}_{\mathbb{P}^5}(3)))$ parameterizing smooth cubics. We have the universal family $\pi : \mathcal{X} \rightarrow B$ of cubic hypersurfaces, where the morphism $\pi$ is smooth and projective. We also have the family $\pi' : VSP \rightarrow B$ which is projective over $B$ but is not smooth. By Proposition 4.1 the general cubic fourfold apolar to a Veronese surface is smooth, so the base $B$ contains the divisor $D_{V \rightarrow \text{ap}}$ parameterizing smooth cubic fourfolds apolar to a Veronese surface. We proved in Theorem 5.1 that for $[f]$ in an open subset $D_{V \rightarrow \text{ap}}^0$, the fiber $VSP(F, 10) = \pi'^{-1}([f])$ has only ordinary quadratic singularities along the surface $S_f$ which is a smooth $K3$ surface. Let $[f]$ be a point of $D_{V \rightarrow \text{ap}}^0$ and let $B^0$ be a Zariski open set of $B$ containing $[f]$ and such that $D_{V \rightarrow \text{ap}}^0 \cap B^0 \subset D_{V \rightarrow \text{ap}}^0$. Let $B' \rightarrow B^0$ be the double cover ramified along $D_{V \rightarrow \text{ap}}^0$. Since $D_{V \rightarrow \text{ap}}^0$ is contained in the smooth locus of $D_{V \rightarrow \text{ap}}$ (cf. Lemma 5.2), the double cover, $B'$, is smooth, and the pulled-back family

$$\pi' : VSP' \rightarrow B'$$

is smooth except along the family of surfaces $S \rightarrow D_{V \rightarrow \text{ap}}^0$, which has codimension $3$ in $VSP'$, and along which $VSP'$ has quadratic nondegenerate singularities. The family $VSP' \rightarrow B'$ can be modified after passing to a degree $2$.

*Documenta Mathematica 22 (2017) 443–492*
étale cover of \( B' \) to a family of smooth complex projective manifolds by a small resolution: For this we first blow-up \( VSP' \) along \( S \) to get \( VSP'' \to B' \). The exceptional divisor \( E \) of the blow-up is a bundle over \( S \) with fibers smooth two-dimensional quadrics. There is an étale double cover \( S \to S \) parameterizing the rulings in the fibers of \( E \to S \). As a K3 surface is simply connected, this double cover comes from a double cover \( D_{V-\text{ap}} \to D_{V-\text{ap}} \). We may assume this étale double cover is induced by an étale double cover \( B^0 \to B^0 \). Performing this base change, the pulled-back family \( VSP'' \to B^0 \) has the property that the inverse image \( \tilde{E} \) of \( E \) admits two morphisms to a \( \mathbb{P}^1 \)-bundle over \( S \). We choose one of them, and as is well-known, we can contract \( \tilde{E} \) to \( S \) along this morphism. The resulting family \( \phi : VSP \to B^0 \) is smooth proper over \( B^0 \).

We now have two families

\[
\phi : \overline{VSP} \to \tilde{B}, \quad \psi : \tilde{X} \to \tilde{B}
\]

of smooth proper complex manifolds, where \( \tilde{X} := X \times_B B^0 \). The fibers of both families are projective, and in particular Kähler, although it is not clear if both morphisms are projective. We thus get two associated variations of Hodge structures on \( B \), one of weight 2 on the primitive cohomology of degree 2 of the fibers of the first family with associated local system \( H^2 \), the other of weight 4 on the primitive cohomology of degree 4 of the fibers of the second family with associated local system \( H^4 \). The locus of points \( b \in B \) where there is a nonzero morphism of Hodge structures \( H^4(\tilde{X}_b, \mathbb{Q})_{\text{prim}} \to H^2(\overline{VSP}_b, \mathbb{Q})_{\text{prim}} \) is the Hodge locus for the induced variation of Hodge structure on the local system \( \text{Hom}(H^4, H^2) \). The Hodge locus is a countable union of closed algebraic subsets of the base \( B \) (cf. [22]). In order to prove Theorem 6.1, it thus suffices to prove that there is a point of \( B \) where there is no nonzero morphism of Hodge structures between \( H^4(\tilde{X}_b, \mathbb{Q})_{\text{prim}} \) and \( H^2(\overline{VSP}_b, \mathbb{Q})_{\text{prim}} \).

By Proposition 4.16, the divisor \( D_{V-\text{ap}} \) is not a Noether-Lefschetz locus for the family \( X \to B \). This means that there exists a point \( b \in D_{V-\text{ap}} \), that we may assume to be in \( D_{V-\text{ap}} \), such that there is no nonzero Hodge class in \( H^4(\tilde{X}_b, \mathbb{Q})_{\text{prim}} \). This fact implies that the Hodge structure on \( H^4(\tilde{X}_b, \mathbb{Q})_{\text{prim}} \) is simple. Indeed, since \( h^{3,1}(\tilde{X}_b) = 1 \), any proper sub-Hodge structure has \( h^{3,1} \)-number 0 or its orthogonal complement for the intersection pairing satisfies this property. In both cases, the existence of a proper sub-Hodge structure implies the existence of a nonzero Hodge class. Note also that it has \( h^{2,1} \)-number equal to 20.

On the other hand, we claim that the transcendental part of \( H^2(\overline{VSP}_b, \mathbb{Q})_{\text{prim}} \) has \( h^{1,1} \)-number \( \leq 19 \). Here the transcendental part is defined as the minimal sub-Hodge structure containing the \( H^{2,0} \)-component.

The claim follows from the fact that \( \overline{VSP}_b \) is hyper-Kähler, being a fiber of a family of Kähler manifolds whose general member is hyper-Kähler, and on the other hand it is the blow-up of \( VSP_b \) along the K3 surface \( S_b \). It thus contains the exceptional divisor \( E_b \) over \( S_b \) and the morphism of Hodge structures.
Variety of Power Sums and Divisors...

$H^2(\tilde{\mathcal{V}}_{\mathcal{S}P_b}, \mathbb{Q}) \to H^2(E_b, \mathbb{Q})$ does not vanish on $H^2(0, \tilde{\mathcal{V}}_{\mathcal{S}P_b})$ because a symplectic form on a fourfold cannot vanish on a divisor. On the other hand, this morphism sends $H^2(\tilde{\mathcal{V}}_{\mathcal{S}P_b}, \mathbb{Q})_{tr}$ to $H^2(E_b, \mathbb{Q})_{tr}$ which is equal to $H^2(S_b, \mathbb{Q})_{tr}$. The induced morphism

$$H^2(\tilde{\mathcal{V}}_{\mathcal{S}P_b}, \mathbb{Q})_{tr} \to H^2(S_b, \mathbb{Q})_{tr}$$

must be injective by the same simplicity argument as above, and thus

$$h^{1,1}(\tilde{\mathcal{V}}_{\mathcal{S}P_b}, \mathbb{Q})_{prim} \leq h^{1,1}(S_b)_{prim} \leq 19.$$

As the Hodge structure on $H^4(X_b, \mathbb{Q})_{prim}$ is simple with $h^{2,2}$-number equal to 20, any morphism of Hodge structures between $H^4(X_b, \mathbb{Q})_{prim}$ and a weight 2 Hodge structure with $h^{1,1}$-number $\leq 19$ is identically 0, which concludes the proof of Theorem 1.6.
