6 Hybrid hydropower and floating photovoltaic power generation has far-reaching effects on
7 the intertwined water, food and energy (WFE) nexus, but the complementary operation is
8 fundamentally challenging especially under high uncertainties of hydro-meteorological
9 conditions. This study proposed an artificial intelligence-based WFE system-overarching
10 solution driven by hybrid hydro-floating photovoltaic power generation for promoting
11 nexus synergies. A multi-objective optimization model grounded upon the Grasshopper
12 Optimization Algorithm was developed to simultaneously maximize hydro-floating
13 photovoltaic power output, the ratio of water storage to reservoir capacity, and the ratio of
14 water supply to water demand. The Shihmen Reservoir watershed and its WFE system in
15 northern Taiwan constituted the case study. The results demonstrated that the proposed
16 optimization model could significantly improve synergistic benefits of the WFE nexus by
17 reaching 13%, 13.3% and 15.1% in water storage, food production and hydro-floating
18 photovoltaic power output, respectively. The optimal tilt angles of floating photovoltaic
19 installation would vary between -11.9° (Summer) and 44.3° (Winter). This study opens up
20 new perspectives on green energy production expansion while stimulating WFE nexus
21 synergies in support of policy-makers with feasible schemes on floating photovoltaic
22 deployment in the interest of social sustainability. In consequence, new niches are exploited
23 for floating photovoltaic deployment and give rise to impact mitigation concerning hydro-
24 meteorological uncertainties on WFE nexus management.

Nomenclature

Abbreviations

AFP	annual food production
APB	annual power benefits
GW	gigawatts
WFE	water-food-energy
MJ	megajoule
MOGOA	multi-objective grasshopper optimization algorithm
MW	megawatts
MWh	megawatts-hour
PHO	floating PV and hydropower output
PV	photovoltaic
RSD	ratio of water supply to water demand
RWS	ratio of water storage to reservoir capacity
SOP	standard operation policy
USD	United States dollars

Indices

t	index of time, from 1 to n
a	index of crops, from 1 to m
i	index of solution in grasshopper population ($i \neq j$), from 1 to N_{pop}
j	index of solution in grasshopper population, from 1 to N_{pop}
k	index of iterations, from 1 to I_{max}
d	index of decision variables, from 1 to D

Parameters

c_{max}	maximal value of the decreasing coefficient
c_{min}	minimal value of the decreasing coefficient
C_T	transformation coefficient from temperature to power for modules of solar cell
D	number of decision variables
f	attraction intensity
g	gravity acceleration
I_{max}	maximal number of iterations
l	attractive length scale
LB_d	lower bound of decision variables in the d -th dimension
m	number of crops
M	number of year
n	number of time step
N_{pop}	size of population
N_{min}^h	minimum hydropower output
N_{max}^h	maximum hydropower output
N_{max}^p	maximum power output of floating PV
N_{min}^{ph}	minimum value of the total power output of floating PV and hydropower
N_{max}^{ph}	maximum value of the total power output of floating PV and hydropower
R_{min}	minimum water release
R_{max}	maximum water release
S_{min}	minimum reservoir storage
S_{max}	maximum reservoir storage
SR_{stc}	solar radiation intensity under standard test conditions
T_{stc}	air temperature of the standard test conditions (25 °C)
UB_d	upper bound of decision variables in the d -th dimension
λ_{IR}	ratio of water supply to water demand of irrigation sector

1		
2		
3		
4	λ_{PUB}	ratio of water supply to water demand of public sector
5	θ_0	specific solar incidence angle under the conditions ($\alpha_t = 0$ and $\gamma = 0$)
6	ϕ	latitude of floating PV deployment
7	γ	azimuth angle of floating PV deployment
8	δ	sun declination angle of floating PV deployment
9	ω	solar hour angle of floating PV deployment
10	η	efficiency coefficient of hydropower plant
11	ρ	density of water
12	Δt	time-step, at a scale of ten days
13	Δt_p	time-step in floating PV power generation (= average sunshine hours in a ten-day period)
14		
15	Δt_h	time-step in hydropower generation at a scale of ten days
16		
17		

Variables

18		
19		
20	A_a	annual irrigation area of the a -th crop
21	$\mathbf{\hat{B}}_d$	vector of the best solution in the d -th dimension
22	c_k	decreasing coefficient at the k -th iteration
23	H_t	hydraulic head of hydro-turbine in the t -th time
24	I_t	reservoir inflow in the t -th time
25	N_t^h	power output of the hydropower in the t -th time
26	N_t^p	power output of the floating PV in the t -th time
27	N_t^{ph}	total output of the floating PV and hydropower in the t -th time
28	PU_a	annual food yield per unit of area (e.g. hectare) of the a -th crop
29	R_t^{ECO}	water release from the reservoir to satisfying river basic eco-flow in the t -th time
30	R_t^{IR}	water release from the reservoir to irrigation sector in the t -th time
31	$R_{t,a}^{\text{IR}}$	water release from the reservoir to the a -th crop in the t -th time
32	R_t^{PUB}	water release from the reservoir to public sector in the t -th time
33	R_t^{SP}	water release through reservoir spillway in the t -th time
34	R_t^{TOTAL}	total water release in the t -th time
35	RT_t	hydro-turbine inflow of hydro-turbine in the t -th time
36	S_t	reservoir storage in the t -th time
37	SR_t^θ	effective solar radiation intensity of the floating PV in the t -th time
38	SR_t	observed solar radiation intensity in the t -th time
39	T_t	air temperature of cell module in the t -th time
40	$\text{WD}_{t,a}^{\text{IR}}$	water demand of the a -th crop in the t -th time
41	WD_t^{IR}	water demand of irrigation sector in the t -th time
42	WD_t^{PUB}	water demand of public sector in the t -th time
43	x_i	current vectors of the i -th grasshopper ($i \neq j$)
44	x_j	current vectors of the j -th grasshopper
45	x_i^d	current vectors of the i -th grasshopper in the d -th dimension
46	x_j^d	current vectors of the j -th grasshopper in the d -th dimension
47	\mathbf{X}_i^d	next position vector of the i -th grasshopper in the d -th dimension
48	θ_t	solar incidence angle in the t -th time
49	α_t	tilt angle of floating PV deployment in the t -th time

1. Introduction

Global population growth, booming economy and urbanization leads to a rapid increase in demands for water, food and energy. The growing demands and interdependences among these precious resources produce stress hotspots in many societies and countries. Water-Food-Energy (WFE) nexus research seeks to explore and minimize tradeoffs among various dimensions of resources consumed by societies. WFE nexus management therefore plays an important role in sustainable development in the context of resource efficiency promotion and environmental threat mitigation. WFE nexus management nowadays attains an unprecedented height and tends to make tradeoffs among demands, purposes, benefits, human beings and environmental sustainability [1,2]. Technological solutions from water-, food-, and energy-driven perspectives [3,4] as well as the mixtures of the three perspectives [5] are being given full play to the reduction of greenhouse gas emission and the improvement of the mutual benefits of WFE sectors. Growths in WFE demands and greenhouse gas emissions compel global energy production to move toward a cleaner path. The collaborative operation among renewable energies (e.g. hydropower, solar power, and wind power) is currently being explored throughout the world to fulfill future targets of green economy [6,7] and sustainable development [8]. Due to meteorological uncertainties, larger output fluctuations appear in solar and wind power generation than in hydropower generation. In this background, owing to the superior regulation ability and flexibility of hydropower operation [9,10], the complementary operation between hydropower and solar power generation is regarded as one of the most promising solutions to increasing energy efficiency [11,12]. Furthermore, floating photovoltaics (PV) deployed on water directly is a rapidly developing emerging technology [13,14] and would be a plausible solution

1
2
3
4 instead of ground-mounted PV due to limited ground space and roof space [15,16].
5
6

7 Traditional ground-mounted PV installation and emerging water-based PV installation
8 are two basic types of PV deployment technologies [17]. In comparison with ground-based
9 PV deployment, water-based PV deployment can be additionally beneficial, such as
10 reducing solar power production costs, increasing the efficiency in temperature regulation
11 of PV modules, lowering water surface evaporation and algae growth, and potentially
12 improving land conservation [18]. Competitive land uses and recognizable synergistic
13 benefits in close relation to water-based floating PV deployment are contributing to
14 facilitating this new niche application and development [19]. Heretofore, man-made water
15 bodies, for instance, wastewater treatment, tailing, retention, and agricultural irrigation
16 ponds and reservoirs, have become predominant sites of floating PV installation [20,21].
17
18 In 2007, the first floating PV system designed by the Japan National Institute of Advanced
19 Industrial Science and Technology was installed in Japan while the first commercial
20 floating PV system designed by the US Thompson Technology Industries was installed at
21 the Far Niente Winery in California [18]. In 2018, the World Bank reported that the global
22 floating PV potential was estimated up to 400 GW (gigawatts) with an installed capacity
23 of approximately 300 MW (megawatts) to date [22]. According to the statistics of global
24 top 100 floating PV projects [23], the total installed capacity reaches as much as 242.89
25 MW, where 98% is contributed by Japan (54%), China (32%), South Korea (8%) and the
26 United Kingdom (4%) (Fig. 1(a)). The top 4 floating PV providers are Ciel & Terre (1st),
27 Reservoir Solar Company (2nd), Takiron Engineering (3rd), and Sumitomo Mitsui
28 Construction (4th) accordingly (Fig. 1(b)).

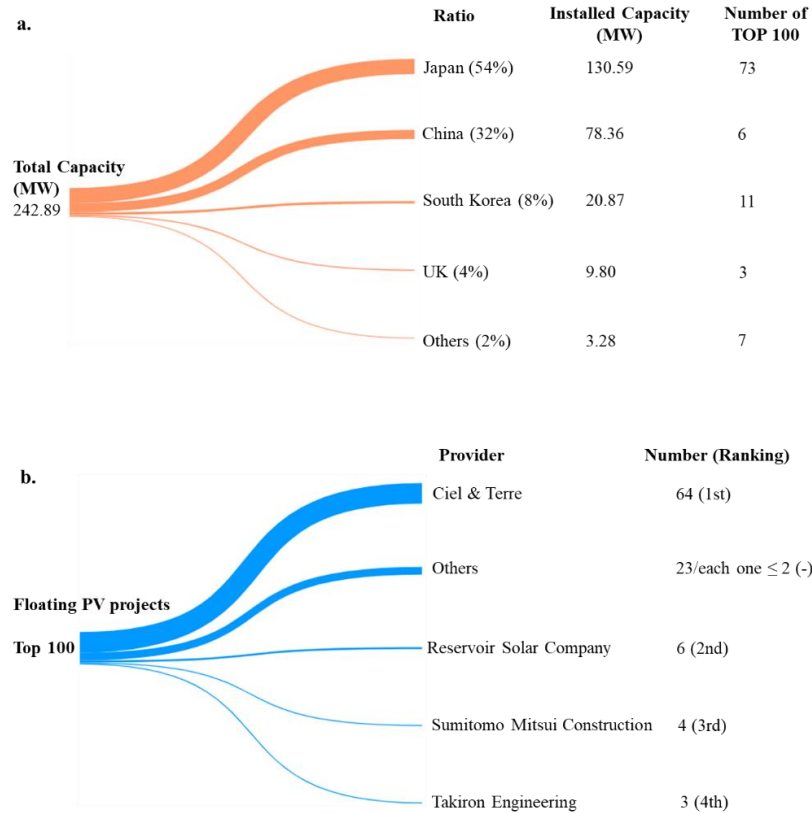

Fig. 1. Statistics of global top 100 floating PV projects. a. profile of installed capacity. b. ranking of floating PV providers. Data extracted from the Global Top 100 Floating Solar Projects [23].

Additionally, the largest (located at Huainan City in China) and the smallest (located at Aisai City in Japan) providers have an installed capacity of 40 MW and 460 kW, respectively. Despite that more and more countries like Japan and China are pursuing the scheme of deploying PV on man-made water bodies [18,23], current water-mounted floating PV projects have installed capacities smaller than ground-mounted ones while floating PV power generation has higher output uncertainty than hydropower generation. Therefore, it is interesting and meaningful to integrate regulatable hydropower generation with non-regulatable PV power generation to pursue their mutual benefits for maintaining stable power supply.

1
2
3
4 The collaborative operation between hydropower and PV (ground- or water-mounted)
5
6 power generation would produce far-reaching influences on WFE nexus management, but
7
8 such complementary implementation is fundamentally challenging because of hydrological
9
10 and meteorological uncertainties and PV power's randomness, intermittency and
11
12 fluctuation [24,25]. Researches with regard to collaborative operation between hydropower
13
14 and PV power generation paid attention mainly to three aspects: optimization of power
15
16 output of hydropower plants [26] and ground-based PV installation (not water-mounted
17
18 PV) [27,28], impact assessment of floating PV deployment at reservoirs on hydropower
19
20 operational flexibility [29] and water quality [30,31], and incorporation of hydropower
21
22 [32,33] and/or PV power generation [34] into hybrid energy systems [35,36] or WFE nexus
23
24 management [37,38]. For instance, Zhang et al. constructed an optimization model for
25
26 chasing the complementary operation between hydropower and ground-mounted PV in
27
28 response to different characteristics of energy demands and reservoir operation [24]. Ming
29
30 et al. combined simulation and optimization approaches to adjust hydropower operation
31
32 rule curves by considering the inputs of photovoltaic power production [25]. Haas et al.
33
34 assessed the impacts of floating PV deployment on reservoir water quality, algal blooms,
35
36 and hydropower output with respect to various water and power price conditions [29].
37
38 Stiubiener et al. proposed a hydropower-floating PV simulation model to improve the
39
40 flexibility of hydropower operation [30]. Château et al. developed a system dynamic
41
42 simulation model for evaluating the potential of floating PV installation over fish ponds
43
44 through searching the optimal percentage of water surface covered by solar panels [31].
45
46 Yang et al. formulated a dynamic programming model to ameliorate the complementary
47
48 operation between hydropower and ground-mounted PV [32]. Wang et al. configured a

3
4 two-objective optimization model to reduce the fluctuations of ground-mounted wind and
5 solar power outputs through hydropower operation [33]. Uen et al. constructed a reservoir
6 optimization model to raise the synergies of the WFE nexus by the collaboration between
7 short-term hydropower operation and long-term water supply from irrigation ponds [37].
8
9 Zhou et al. proposed a bi-objective optimization model to improve WFE nexus
10 management through optimizing multi-sectoral water allocation and small-hydropower
11 deployment [38].
12
13
14
15
16
17
18
19
20

21 Research gaps among the aforementioned aspects were summarized. From the
22 standpoint of water-mounted PV application, previous researches mainly concentrated
23 either on ecological assessment using simulation techniques or on the optimal design of
24 solar panels whereas few involved the optimization of hydropower and floating PV power
25 outputs. From the standpoint of WFE nexus optimization (i.e. tri-objective optimization),
26 previous researches focused either on bi-objective optimization techniques or on
27 decomposition optimization techniques whereas few directly involved tri-objective
28 optimization techniques. In other words, bi-objective and/or decomposition optimization
29 techniques commonly decomposed a tri-objective optimization problem into several sub-
30 optimization problems (i.e. a single-objective sub-problem and a bi-objective sub-problem,
31 or three single-objective sub-problems), yet they would not solve the tri-objective
32 optimization problem directly.

50 The novelty of this study relies upon the optimization of both floating PV deployment
51 on irrigation ponds and existing hydropower operation using an innovative artificial
52 intelligence technique, meanwhile, its application for the first time to spur on the synergies
53 of the WFE nexus. Main contributions could be attributed to three aspects. First, the
54
55
56
57
58
59
60
61
62
63
64
65

1
2
3
4 mathematical model for tri-objective optimization was configured to simultaneously
5 maximize hydropower and floating PV power outputs, the ratio of water storage to
6 reservoir capacity, and the ratio of water supply to water demand. Second, the optimal
7 hydropower generation, floating PV deployment, and multi-sectoral water allocation under
8 various hydrological and meteorological conditions were obtained by adopting a nature-
9 inspired optimization algorithm. Third, WFE synergies relating to the optimal solutions
10 were acquired from the optimal hydropower operation in connection to the optimal floating
11 PV deployment under three representative scenarios constituted by various hydrological
12 and meteorological conditions. The theoretical framework proposed in this study not only
13 creates new niches on green energy production and promotes WFE nexus synergies but
14 also supports policy-making with feasible schemes on floating photovoltaic deployment in
15 the interest of social sustainability. The Shihmen Reservoir and its WFE system in northern
16 Taiwan formed the case study.

37 38 **2. Study area and materials**

39
40 Fig. 2 illustrates the schematic diagram of the water supply system (including irrigation
41 ponds), agricultural irrigation areas and energy generation facilities located in the Shihmen
42 Reservoir watershed. The Shihmen Reservoir situated in northern Taiwan is the pivotal
43 infrastructure serving multiple purposes for the Taipei and Taoyuan metropolitan areas as
44 well as the Taoyuan and Shihmen irrigation areas. This reservoir embraces a watershed
45 area of 763 km² and has an effective storage capacity of 203 million m³. The maximum
46 storage of the conservation pool (208 million m³) corresponds to its normal water level
47 (245 m) while the dead storage of the inactive pool (5 million m³) corresponds to its dead

64
65

water level (195 m). This multi-purpose reservoir is operated to meet water demands of public and irrigation sectors, produce hydroelectricity, and implement flood prevention tasks, where each of the six floodgates and the two tunnel spillways holds its maximal discharge capacity of 11400 m³/s and 2400 m³/s, respectively. Two hydropower units installed in the Shihmen hydropower station of the reservoir have a total installed capacity of 90 megawatts (= 2*45 MW), an annual power output of 230 million kWh, and the maximal discharge of 137.2 m³/s (= 2*68.6 m³/s).

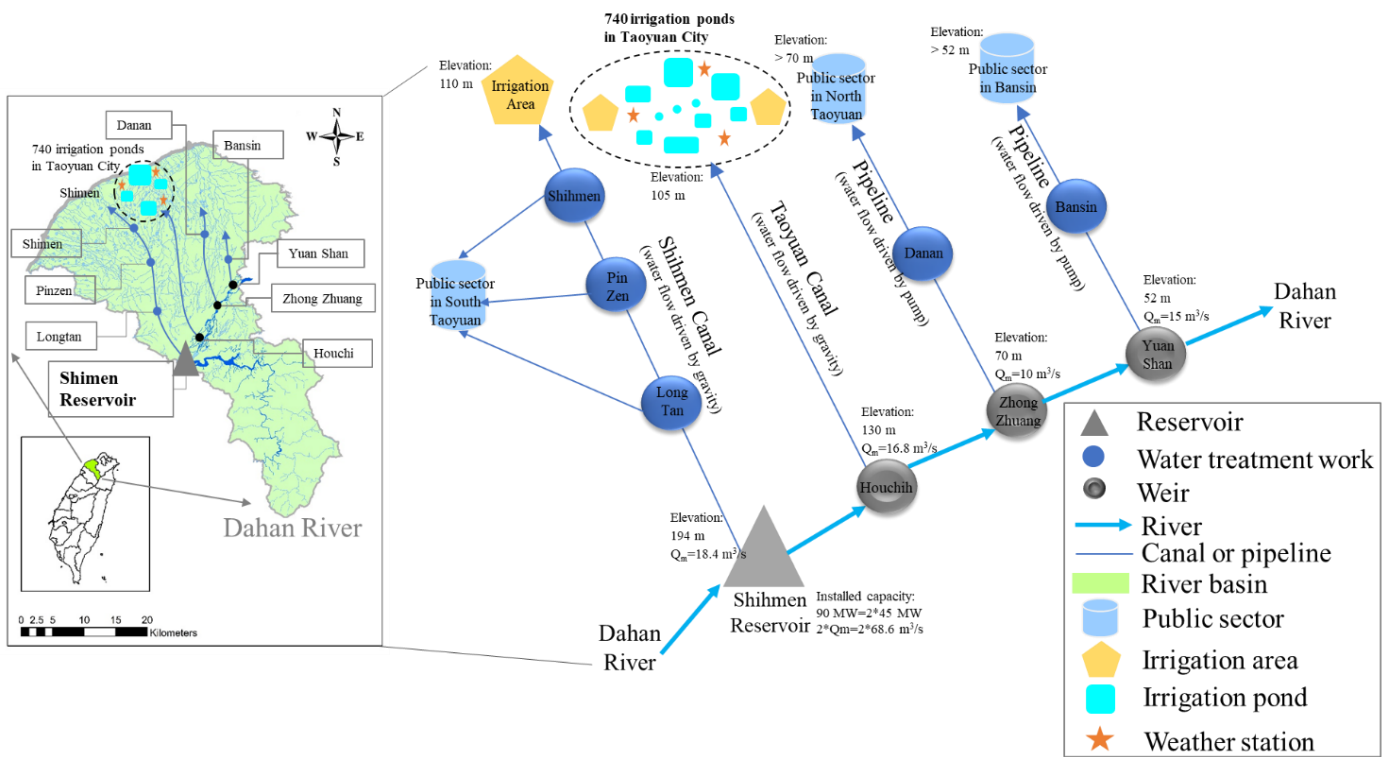

Fig. 2. Schematic diagram of the water supply system (including irrigation ponds), agricultural irrigation areas, and energy generation facilities located in the Shihmen Reservoir watershed, where floating PV devices would be deployed over 740 irrigation ponds in Taoyuan City. Q_m is the maximum discharge.

The Shihmen watershed contains the Dahan River basin and tributary basins, where the Taoyuan and Shihmen irrigation areas occupy 270 km² and 121 km², respectively. The

1
2
3
4 mean annual precipitation of this watershed is close to 2500 mm, and seasonality of
5
6 typhoon-induced floods spans from July to September basically. The routine operation of
7
8 the Shihmen Reservoir is managed to supply water to various demanding sectors. Water
9
10 released from the reservoir travels through the watershed via the Shihmen hydropower
11
12 station, the Houchih Weir, and weirs located in the Dahan River whilst water also
13
14 discharges from the reservoir into the Shihmen Canal to meet the water demands of public
15
16 and irrigation sectors in South Taoyuan (Fig. 2). The remaining water would be released
17
18 from spillway gates to the Houchih Weir as soon as possible when the water demands of
19
20 public and irrigation sectors in the study area excluding South Taoyuan surpass the
21
22 maximal discharge capacity ($137.2 \text{ m}^3/\text{s}$) of the two hydropower plants.
23
24
25
26
27

28 *Standard Operation Policy (SOP)*

29
30
31 The authority of the Shihmen Reservoir will perform M-5 rule curves [37] if water
32
33 conflicts occur between public and irrigation sectors. The SOP is introduced briefly, shown
34
35 below.
36
37

- 38 (a) The water supply system would completely meet water demands when the storage
39
40 capacity of the Shihmen Reservoir is higher than the lower limit curve. Accordingly, the
41
42 ratio (λ_{IR}) of water supply to irrigation water demands is equal to 1 meanwhile it is the
43
44 same for the public sectors ($\lambda_{\text{PUB}}=1$).
45
46
47
- 48 (b) The values of λ_{PUB} and λ_{IR} are equal to 0.9 and 0.75, respectively, when the storage
49
50 capacity of the Shihmen Reservoir situates between the critical lower limit curve and
51
52 the lower limit curve.
53
54
- 55 (c) The values of λ_{PUB} and λ_{IR} are equal to 0.8 and 0.5, respectively, when the storage
56
57 capacity of the Shihmen Reservoir falls below the critical lower limit curve.

Floating PV deployment

A great deal of (740) irrigation ponds (volume of each pond ≥ 20 m (length)*5 m (width)*1 m (depth)) distributed across Taoyuan City possess an approximate cumulative capacity of 62 million m³ and a total area of 12 km² (Fig. 2), and they would be regarded as the water bodies suitable for floating PV deployment (Fig. 3). The annual sunshine duration in Taoyuan City varies between 1400 and 2200 hours. In this study, the deployment of floating PV systems did not consider the impacts of PV types and their combinations on power output while the percentage of water surface of a pond covered with the floating PV system was set as 40% (i.e. installed area-to-pond area ratio) according to our previous study and the official announcement regarding the maximal pond area allowing PV deployment in Taiwan [31]. A floating solar system with Hydrelion polyethylene designed by Ciel & Terre (<https://www.ciel-et-terre.net/>) is considered for floating PV installation over these 740 ponds in this study. The Neo Solar power (DP310B4A) solar panel installed in this floating PV system (Fig. 3(a)) embraces an installed capacity of 310 W/unit, a size of 1.5 m²/unit (= 1.5 m (length)* 1 m (width)), a tilt angle (α) relative to the horizontal, and a cost of 80 USD/unit (<https://www.ciel-et-terre.net/>). Consequently, in the case of an installed area-to-pond area ratio of 40%, a total installed capacity of 992 MW (= 12 (km²)*40%/(1.5 m²)*310 (W)) would be deployed over the 740 ponds (total area = 12 km²) in Taoyuan City.

a. Sketch map of floating PV deployment

b. Optimal tilt angle scheme with seasonal variation

c. Traditional floating PV deployment using horizontal installation

Fig. 3. Illustration of the floating PV system with an installed area-to-pond area ratio of 40% deployed over 740 irrigation ponds in Taoyuan City (α is the tilt angle of the floating PV deployment, relative to the horizontal). a. sketch map of floating PV deployment. b. Optimal tilt angle scheme with seasonal variation. c. traditional scheme of floating PV deployment under horizontal installation served as the benchmark.

In our previous study [31], both experimental comparison and mathematical simulation would lay a solid foundation for the high potential and practicality to deploy floating PV on ponds. Besides, based on the experimental data collected from ponds with (an installed area-to-pond area ratio of 40%) or without floating PV cover, the ecological impact assessment pointed out that the deployment of floating PV on ponds only has a

1
2
3
4 small negative impact on water quality by reason of a slight reduction in dissolved oxygen
5 levels. The goal of floating PV deployment in this study was to search the optimal seasonal
6 tilt angles to make a significant gain in solar radiation for maximizing solar panel efficiency
7 (Fig. 3(b)). Additionally, the traditional scheme of floating PV deployment under
8 horizontal installation (tilt angle = 0°) served as the benchmark (Fig. 3(c)). The purchase
9 prices of hydropower and solar power in Taiwan in 2018 were 67 USD/MWh and 170
10 USD/MWh, respectively.

1
2
3
4 nexus was configured at first by three objectives and relevant constraints so as to lift the
5
6 floating PV and hydropower output, water supply reliability, and food production at the
7
8 same time (Fig. 4(a)). Then the synergistic benefits of the WFE nexus were optimized using
9
10 the Multi-objective Grasshopper Optimization Algorithm (MOGOA, Fig. 4(b)) driven by
11
12 15-year hydrological and meteorological circumstances at a ten-day scale. The methods
13
14 adopted in this study are introduced briefly as follows.
15
16
17
18

19 ***3.1 Multi-objective optimization model of water-food-energy nexus***

20
21 To tackle water-food-energy nexus challenges by increasing renewable power output
22
23 meanwhile raising synergies between water and food sectors, this study proposes a multi-
24
25 objective optimization model. The objective functions and variables of the mathematical
26
27 model are summarized in Table 1. This model (Fig. 4(a)) is configured with Objective 1:
28
29 maximization of average annual floating PV and hydropower output (PHO); Objective 2:
30
31 maximization of average annual ratio of water storage to reservoir capacity (RWS); and
32
33 Objective 3: maximization of average annual ratio of water supply to water demand of both
34
35 public and irrigation sectors (RSD). The operation of hydropower plants should satisfy
36
37 physical constraints, consisting of the reservoir water balance equation (Eq. (7)), the
38
39 reservoir water release equation (Eq. (8)), the feasible boundaries of reservoir water release,
40
41 reservoir storage capacity, and power output (Eqs. (9a), (9b) & (9c), respectively), as well
42
43 as reservoir operation rules (Eqs. (10a) & (10b)), meanwhile, floating PV operation should
44
45 obey the feasible boundaries of power output (Eq. (11)). Additionally, the plants of floating
46
47 PV and hydropower should obey the feasible boundaries of power grid operation (Eq. (12)).

Objective function	Item
Maximize PHO = $\frac{1}{M} \cdot \sum_{t=1}^n N_t^{ph} \cdot \Delta t = \frac{1}{M} \cdot (\sum_{t=1}^n N_t^p \cdot \Delta t_p + \sum_{t=1}^n N_t^h \cdot \Delta t_h)$	(1) Objective 1: PHO
$N_t^p = N_{max}^p \cdot \left(\frac{SR_t^\theta}{SR_{stc}}\right) \cdot [1 + C_T \cdot (T_t - T_{stc})]$	(2a)
$SR_t^\theta = SR_t \cdot \frac{\cos\theta_t}{\cos\theta_0}$	(2b)
$\cos\theta_t = (\sin\phi \cdot \cos\alpha_t - \cos\phi \cdot \cos\gamma \cdot \sin\alpha_t) \cdot \sin\delta + (\cos\phi \cdot \cos\alpha_t + \sin\phi \cdot \cos\gamma \cdot \sin\alpha_t) \cdot \cos\delta \cdot \cos\omega + \sin\gamma \cdot \cos\delta \cdot \sin\omega \cdot \sin\alpha_t$	(2c)
$\cos\theta_0 = \sin\phi \cdot \sin\delta + \cos\phi \cdot \cos\delta \cdot \cos\omega$	(2d)
$N_t^h = \eta \cdot \rho \cdot g \cdot RT_t \cdot H_t$	(3)
Maximize RWS = $\frac{1}{M} \sum_{t=1}^n \left(\frac{S_t}{S_{max}}\right)$	(4) Objective 2: RWS
Maximize RSD = $\frac{1}{M} \cdot \sum_{t=1}^n \left(\frac{R_t^{IR} + R_t^{PUB}}{WD_t^{IR} + WD_t^{PUB}}\right)$	(5) Objective 3: RSD
$AFP = \frac{1}{M} \cdot \sum_{a=1}^m \left(\frac{\sum_{t=1}^n R_{t,a}^{IR} \cdot PU_a \cdot A_a}{\sum_{t=1}^n WD_{t,a}^{IR}}\right)$	(6a)
$R_t^{IR} = \begin{cases} WD_t^{IR}, & \text{if } (R_t^{IR} > WD_t^{IR}) \\ R_t^{IR}, & \text{else} \end{cases}$	(6b)
$\sum_{a=1}^m R_{t,a}^{IR} = R_t^{IR}, \quad \sum_{a=1}^m WD_{t,a}^{IR} = WD_t^{IR}$	(6c)
$R_t^{PUB} = \begin{cases} WD_t^{PUB}, & \text{if } (R_t^{PUB} > WD_t^{PUB}) \\ R_t^{PUB}, & \text{else} \end{cases}$	(6d)
Constraints	Item
$S_{t+1} = S_t + (I_t - R_t^{TOTAL}) \cdot \Delta t$	(7) Water balance equation
$R_t^{TOTAL} = R_t^{IR} + R_t^{PUB} + R_t^{ECO} + R_t^{SP}$	(8) Water release equation
$R_{min} \leq R_t^{TOTAL} \leq R_{max}$	(9a) Water release boundary
$S_{min} \leq S_t \leq S_{max}$	(9b) Storage capacity boundary
$N_{min}^h \leq N_t^h \leq N_{max}^h$	(9c) Power output boundary
$R_t^{PUB} = WD_t^{PUB} \cdot \lambda_{PUB}$	(10a) Reservoir operation rules
$R_t^{IR} = WD_t^{IR} \cdot \lambda_{IR}$	(10b) Reservoir operation rules
$0 \leq N_t^p \leq N_{max}^p$	(11) Floating PV boundary
$N_{min}^{ph} \leq N_t^{ph} \leq N_{max}^{ph}$	(12) Power grid boundary

In objective 1:

N_t^p , N_t^h , and N_t^{ph} are the power output (megawatt, MW) of floating PV, the power output of the hydropower, and the total power output of floating PV and hydropower in the t -th time, respectively. n and M are the number of time steps and the number of years, respectively. Δt is the length of the time step (hours), and its value is set as ten-day ($\Delta t = \Delta t_h = 240$ hours) for hydropower generation while being set as average sunshine hours ($= \Delta t_p$) in a ten-day period for floating PV power generation. N_{max}^p is the maximum power output (MW) of floating PV. SR_t , SR_t^θ and SR_{stc} are the observed solar radiation intensity (MJ/m² (megajoule)) in the t -th time, the effective solar radiation intensity of floating PV with a solar incidence angle θ in the t -th time, and the solar radiation intensity under the standard test condition (i.e. temperature = 25 °C), respectively. C_T is the transformation coefficient (/) from temperature to power for the modules of the solar cell. T_t and T_{stc} are the air temperature (°C) of the cell module in the t -th time and the air temperature of the standard test condition (25 °C), respectively. α_t is the tilt angle (°) of the floating PV deployment relative to the horizontal in the t -th time. ϕ , γ , δ , and ω are the latitude, the azimuth angle (°), the sun declination angle (°), and the solar hour angle (°) of floating PV, respectively, and they are constants for each pond. θ_t and θ_0 are the solar incidence angle (°) in the t -th time and the specific solar incidence angle (°) under the condition ($\alpha_t = 0$ and $\gamma = 0$), respectively. η , ρ , and g are the efficiency coefficient (/) of the hydropower plant, water density (kg/m³), and gravity acceleration (m/s²), respectively. RT_t and H_t are the hydro-turbine inflow (m³/s) and the hydraulic head (m) of the hydro-turbine in the t -th time, respectively. Eq. (2a) is modified according to the previous version developed by the U.S. National Renewable Energy Laboratory (NREL, <https://www.nrel.gov/>).

In objective 2:

S_t and S_{max} are the reservoir storage (m³) in the t -th time and the maximum reservoir capacity (m³), respectively. AFP and RSD are the annual food production (kg) and the ratio (/) of water supply to water demand in irrigation and public sectors, respectively.

In objective 3:

PU_a and A_a are the annual food yield (kg) of the a -th crop per unit area (hectare) and the annual irrigation area (hectare) of the a -th crop, respectively, and the crops involve rice, vegetables, and fruits in this study. m is the number of crops ($m = 4$, in this study). $R_{t,a}^{IR}$, R_t^{IR} , $WD_{t,a}^{IR}$, WD_t^{IR} , R_t^{PUB} , and WD_t^{PUB} are the water release (m^3/s) from the reservoir to the a -th crop, the water release (m^3/s) from the reservoir to irrigation sectors, the water demand (m^3/s) of the a -th crop, the water demand (m^3/s) of irrigation sectors, the water release (m^3/s) from the reservoir to public sectors, and the water demand (m^3/s) of public sector in the t -th time, respectively. In this study, food production is considered as a mathematical function (Eq. (6a)) of food yield per unit area, irrigation area, and ratio of water supply to water demand variables, ignoring the impacts of sunlight and fertilization on food yield [39].

In constraints:

S_t and I_t are the reservoir storage (m^3) and reservoir inflow (m^3/s) in the t -th time, respectively. R_t^{IR} , R_t^{PUB} , R_t^{ECO} , R_t^{SP} , and R_t^{TOTAL} are the water releases (m^3/s) from the reservoir to irrigation sectors, to public sectors, to satisfy ecological needs (river base flow), through reservoir spillways, and the total water release in the t -th time, respectively. R_{min} and R_{max} are the minimum and maximum water release (m^3/s), respectively. S_{min} and S_{max} are the minimum and maximum reservoir storage (m^3), respectively. N_{min}^h and N_{max}^h are the minimum and maximum hydropower output (MW), respectively. WD_t^{PUB} and WD_t^{IR} are the water demands (m^3/s) of public and irrigation sectors in the t -th time, respectively. N_{max}^p is the maximum power output (MW) of the floating PV. N_{min}^{ph} and N_{max}^{ph} are the minimum and maximum total power outputs (MW) of floating PV and hydropower, respectively, while the latter relies on the maximal transmission capacity of the transmission line of the power grid.

According to the mathematical equations of this multi-objective optimization model, the first objective function (Eq. (1)) is closely linked with the decision variables of the tilt angle (α_t) of floating PV deployment and the reservoir water release through the hydro-turbine (RT_t), the second objective function (Eq. (4)) is closely associated with the decision variables of water release from reservoir to various water demanding sectors, and the third objective function (Eq. (5)) is closely related to the decision variable of water release from reservoir to irrigation and public sectors (R_t^{IR} & R_t^{PUB}). That is to say, this model aims at searching for the optimal tilt angle (α_t) of the floating PV deployment and the optimal reservoir water releases to increase the synergistic benefits of the WFE nexus. The next section would introduce a multi-objective optimization algorithm to solve the proposed optimization model.

3.2 Multi-objective Grasshopper Optimization Algorithm (MOGOA)

The MOGOA firstly proposed by Mirjalili et al. [40] is an evolutionary algorithm derived

1
2
3
4 from the single-objective Grasshopper Optimization Algorithm [41]. The MOGOA models
5 and mimics the interactive behavior of grasshopper swarm (Fig. 4(b)) characterizing
6 attraction force, repulsion force, and comfort zone in nature for solving multi-objective
7 optimization problems. The MOGOA has demonstrated its robustness and superiority in
8 the optimization of multi-objective problems through testing various Pareto optimal fronts,
9 including linear, nonlinear, convex, concave as well as separated ones [40], in comparison
10 to well-recognized and popular multi-objective algorithms in the literature such as Non-
11 dominated Sorting Genetic Algorithm-II [42], Multiple-objective Particle Swarm
12 Optimization [43], Multi-objective Ant Colony Optimization [44], Multi-objective
13 Differential Evolution [45], and Multi-objective Evolution Strategy [46].

This study would center on the exploration of the MOGOA for optimizing the WFE
nexus, rather than on the comparison of various multi-objective optimization algorithms.
That is to say, the MOGOA is implemented for the first time to provide energy-driven WFE
nexus solutions through concurrently searching the optimal tilt angle (α_t) of floating PV
deployment and the optimal reservoir operations needed to maximize the PHO (Eq. (1)),
the RWS (Eq. (4)) and the RSD (Eq. (5)) during 2004 and 2019 (= 15 years). The
implementation procedure of the MOGOA is illustrated in Fig. 4(b) and described as
follows.

Step 1: Initialize a population of search agents (i.e. grasshopper swarm) possessing a size
of N_{pop} randomly; and set the values of parameters of the maximal and minimal
values of the decreasing coefficient and the maximal number of iterations. Real-
coded solutions are used for the decision variables of the tilt angle (α_t) and reservoir
water releases (R_t^R & R_t^{PUB}).

Step 2: Evaluate the fitness values of grasshopper swarm; conduct the fast non-dominated sorting for partitioning the grasshopper population into various ranks; compute the crowding distance of the grasshopper population; implement the roulette wheel operation to select the best solution possessing a higher value of fitness (i.e. the elitism preserving strategy) for creating an offspring of the grasshopper population.

The size of the offspring population in every iteration should be N_{pop} .

Step 3: For the k -th iteration, update the value of the decreasing coefficient using Eq. (13); map the distance between every two grasshoppers onto the interval of $(0, 15]$ to divide the space between grasshoppers into the attraction zone $(0, 1]$, the comfort zone $(1, 4]$ and the repulsion zone $(4, 15]$; create the next positions of the grasshopper swarm using Eq. (14); and bring back the current grasshopper swarm if the swarm go outside the boundaries (e.g. $(0, 15]$).

$$c_k = c_{\max} - k \cdot \frac{(c_{\max} - c_{\min})}{I_{\max}} \quad (13)$$

$$\mathbf{X}_i^d = c_k \cdot \left(\sum_{\substack{j=1 \\ j \neq i}}^{N_{\text{pop}}} c_k \cdot \frac{(UB_d - LB_d)}{2} \cdot s(\|\mathbf{x}_j^d - \mathbf{x}_i^d\|) \cdot \frac{(x_j - x_i)}{\|\mathbf{x}_j - \mathbf{x}_i\|} \right) + \widehat{\mathbf{B}}_d \quad (14a)$$

$$s(x) = f \cdot e^{\frac{-x}{i}} - e^{-x} \quad (14b)$$

where c_k is the decreasing coefficient to minify the repulsion zone, comfort zone and attraction zone at the k -th iteration. c_{\max} and c_{\min} are the maximal and minimal values of c_k , respectively. \mathbf{X}_i^d is the next position vector of the i -th grasshopper in the d -th dimension ($d = 1, 2, \dots, D$, and D is the number of decision variables) and is derived from its current position, the position of the best solution, as well as the positions of all other grasshoppers. UB_d and LB_d are the upper and lower bounds of decision variables in the d -th dimension, respectively. \mathbf{x}_i^d and \mathbf{x}_j^d are the current vectors of the i -th grasshopper and the j -th

grasshopper in the d -th dimension, respectively. \mathbf{x}_i and \mathbf{x}_j are the current vectors of the i -th grasshopper and the j -th grasshopper, respectively. $\|\mathbf{x}_j^d - \mathbf{x}_i^d\|$ is the distance between the i -th grasshopper and the j -th grasshopper in the d -th dimension. $\frac{(\mathbf{x}_j - \mathbf{x}_i)}{\|\mathbf{x}_j - \mathbf{x}_i\|}$ is the unit vector from the i -th grasshopper to the j -th grasshopper. $\widehat{\mathbf{B}}_d$ is the vector of the best solution in the d -th dimension. $s(x)$ is defined as the function of social forces with variable x while the parameters of f and l are the attraction intensity and the attractive length scale, respectively.

Step 4: Terminate the calculation in accordance with stop criteria by assessing the solutions through Steps 2-4. If the iteration number is less than the maximum iteration (I_{\max}), then perform Steps 2-4 repeatedly. Otherwise, stop iteration as well as output the optimization results.

The MOGOA model built for WFE nexus optimization is driven by a total of 1728 datasets (= 3 variables (reservoir inflow, solar radiation intensity and temperature)*36 ten-day periods*15 years + 3 water demands (public, irrigation and river basic eco-flow)*36 ten-day periods), 1620 decision variables (= 3 variables*36 ten-day periods*15 years), and 4860 constraints (= 540*7 (hydropower) + 540*2 (floating PV)) (Fig. 4(b)). To obtain converged results, a trial-and-error procedure is carried out intensively to configure the parameters of the MOGOA. Therefore, the values of the population size (N_{pop}), the maximum iteration (I_{\max}), the maximum and minimum decreasing coefficients (C_{\max} , C_{\min}), the attraction intensity (f), and the attractive length scale (l) are set as 1000, 500, 1, 0.0001, 0.5, 1.5 respectively, where each solution involves 1620 decision variables in this case.

4. Results and discussion

1
2
3
4 Fast development of urbanization and industrialization has triggered huge crises and
5
6 challenges in the nexus management on water, food and energy demands. This study
7
8 centered on probing into long term complementary operation between floating PV and
9
10 hydropower to boost the synergistic benefits of the WFE Nexus with the use of artificial
11
12 intelligence-based heuristic techniques. The details of results and key findings were
13
14 presented and elaborated in three perspectives: optimization of water-food-energy nexus
15
16 using MOGOA; synergy analysis of water-food-energy nexus; and summarization.
17
18
19
20

21 22 ***4.1 Optimization of water-food-energy nexus using MOGOA*** 23

24 The main objective of this study is to probe into the synergistic benefits of the WFE nexus
25
26 motivated by floating PV and hydropower output optimization with the use of a novel
27
28 nature-inspired algorithm (i.e. MOGOA) under a specified multiple-year (2004-2019)
29
30 scenario at a temporal scale of ten days. Besides, a simulation-based approach (i.e. Eq. (2))
31
32 with the tilt angle $\alpha_t=0^\circ$, Fig. 3(c)) was adopted for calculating the floating PV power
33
34 output while the Standard Operation Policy (SOP)-based approach (M-5 rule curves) was
35
36 applied to estimating the outputs of water, food and hydropower, where the non-
37
38 optimization technique (i.e. the combination of simulation-based and SOP) served as the
39
40 benchmark for comparison purpose.
41
42
43
44

45
46 Fig. 5(a) displayed 1000 non-dominated solutions concerning the multiple-year
47
48 scenario, where solutions were distributed independently on the Pareto optimal front of
49
50 three objectives (PHO, RWS and RSD) meanwhile converged at the 500th iteration. To
51
52 better express the distribution pattern of Pareto optimal solutions, a surface interpolation
53
54 was conducted over these discrete 1000 solutions (Fig. 5(a)). The resulting Pareto front
55
56 surface displays a pretty smooth and upward convex shape, and the 1000 solutions well-fit
57
58
59
60
61
62
63
64
65

1
2
3
4 the interpolated surface. The results clearly pointed out the three objectives (PHO, RWS,
5 and RSD) competed with each other. For instance, larger floating PV and hydropower
6 outputs (PHO) would be accompanied in pace with smaller water storage volumes (RWS)
7 and/or lower water supply reliability (RSD), and vice versa. That is to say, Solution A
8 tended to be the circumstance completely dominated by PHO, Solution B was inclined to
9 be the circumstance completely dominated by RWS, whereas Solution C seemed to be the
10 circumstance completely dominated by RSD. The remaining solutions such as Solution D
11 were marked as compromised solutions to facilitate tradeoffs among the three objectives.
12
13
14
15
16
17
18
19
20
21
22

23 The results demonstrated that the MOGOA could search and approximate to the best
24 non-dominated solutions for the multi-objective optimization of the WFE nexus because
25 of the solutions spreading with high coverage and superior diversity across three objectives
26 (Fig. 5(a)) as well as the excellent convergence ability (Figs. 5(b)-(d)). The reasons for the
27 MOGOA's good performance are summarized here. First, the high coverage is owing to
28 the mechanism of target selection. Second, the superior diversity benefits from avoiding an
29 overcrowded repository by discarding and replacing non-dominated solutions with new
30 ones. Last but not the least, the excellent convergence ability is ascribed to the adaptive
31 mechanism that stimulates the grasshoppers' behaviors in the direction of the Pareto
32 optimal solutions.

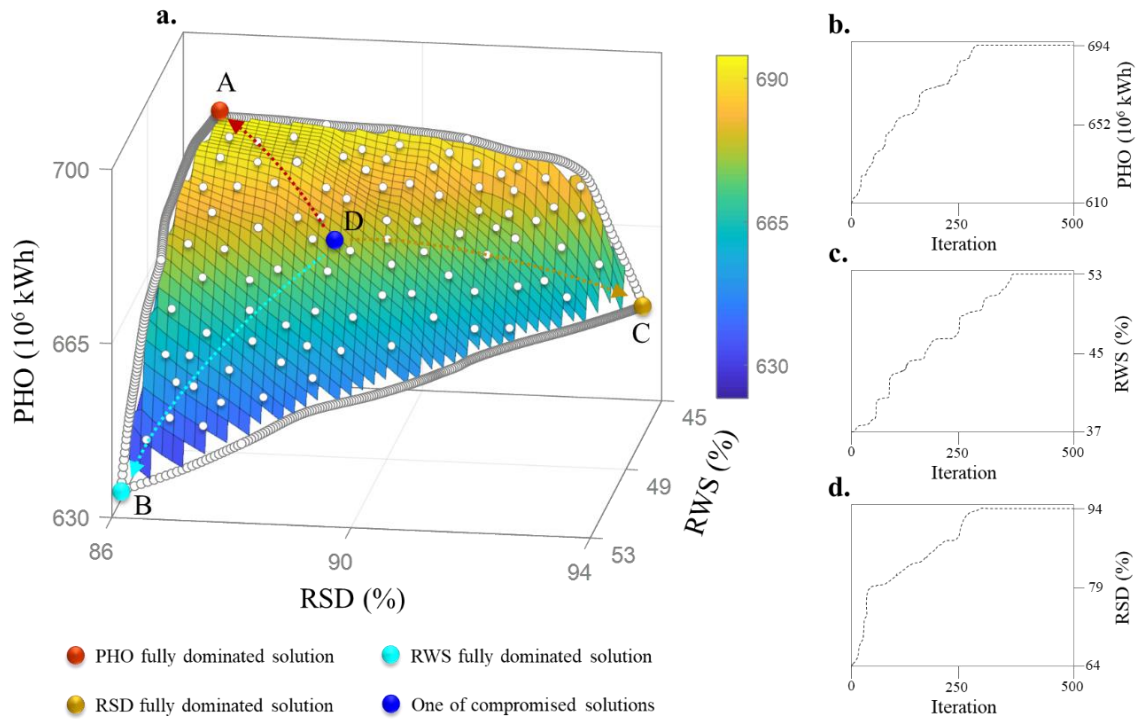

Fig. 5. Pareto front of the MOGOA (converged at the 500th iteration) concerning the floating PV and hydropower output (PHO), the ratio of water storage to reservoir capacity (RWS), and the ratio of water supply to water demand (RSD) under a multiple-year scenario (2004-2019). a. Optimal solutions to WFE nexus management, where the Pareto front surface interpolated was colored with gradient color. b-d. Iteration performance with respect to three objective functions.

Table 2 presented the optimal outputs of water, food and energy acquired from the MOGOA under the multiple-year scenario. It was easy to find that the MOGOA produced much better performances (larger RWS and RSD values, and higher average annual floating PV and hydropower output) than the non-optimization technique that combined simulation-based and SOP approaches. The results demonstrated that the optimal MOGOA solutions would substantially lift reservoir storage (RWS), significantly improve water supply reliability (RSD), and effectively increase floating PV and hydropower output (PHO) at the same time. The compromised solution (Solution D) could increase RWS, RSD and PHO by 6.5%, 8.4% and 12.4%, respectively. Additionally, the maximal improvement rates

in PHO (15.1%), RWS (13%), and RSD (13.3%) corresponded to the individual solutions under the circumstances completed dominated by PHO (Solution A), RWS (Solution B), and RSD (Solution C), respectively. In other words, the obtainments of the solutions completely dominated by PHO (Solution A), RWS (Solution B), and RSD (Solution C) were to implement the solution search in the directions towards maximizing PHO, RWS, and RSD, respectively. It was an interesting finding that the ranges of improvement rates in water (2.2%–13%), food (3.6%–13.3%) and energy (4.8%–15.1%) sectors were similar. This could be contributed by the synergistic optimization capability of the MOGOA, different from the optimization with just one objective or two objectives gaining top priority.

Table 2 Water, food, and energy outputs acquired from the MOGOA optimization (Fig. 5(a)) and the non-optimization technique under the multiple-year scenario.

Objective	Indicator	MOGOA ^a Pareto Optimal Solutions				Non-optimization ^b (benchmark)
		A	B	C	D	
Water	RWS ^c	48 (4.3 ^f)	52 (13.0)	47 (2.2)	49 (6.5)	46
Food	RSD ^d	87 (4.8)	86 (3.6)	94 (13.3)	90 (8.4)	83
Energy	PHO ^e	694 (15.1)	632 (4.8)	656 (8.8)	678 (12.4)	603

^a Multi-objective Grasshopper Optimization Algorithm.

^b A combination of simulation-based and Standard Operation Policy (SOP) approaches, where the simulation-based approach (i.e. Eq. (2) and the tilt angle $\alpha_t=0$) was adopted for calculating the floating PV output while the SOP-based approach (M-5 rule curves) was applied to estimating the outputs of water, food and hydropower.

^c Average annual ratio of water storage to reservoir capacity (%).

^d Average annual ratio of water supply to water demand (%) (\equiv annual food production).

^e Average annual floating PV and hydropower output (10^6 kWh).

^f Improvement rate (%), and the benchmark was the non-optimization technique.

Fig. 6 further illustrated the competition between objectives in pairs: (a) energy versus water; (b) energy versus food; and (c) water versus food. Point A represents the optimal solution merely maximizing the floating PV and hydropower output (Objective 1).

1
2
3
4 Point B represents the optimal solution exclusively deliberating water storage (Objective
5
6
7 2). Point C represents the optimal solution only considering water supply reliability
8
9 (Objective 3). Point D represents a comprised solution. With the optimal solutions on hands,
10
11 members of think tanks could effectively provide decision-makers with deliberate
12
13 strategies to wisely manage the intensive conflicts among energy, food and water
14
15 demanding sectors encountering various meteorological and hydrological conditions. For
16
17 example, the optimal solutions close to Solution A were prone to maximizing the energy
18
19 output (PHO), suggesting it would be adequate to implement floating PV deployment
20
21 schemes and reservoir operation strategies corresponding to these optimal solutions in
22
23 years with high solar radiation intensity and abundant precipitation, respectively. The
24
25 optimal solutions close to Solution B was inclined to maximize the water storage (RWS),
26
27 indicating it would be adequate to implement floating PV deployment schemes and
28
29 reservoir operation strategies associated with these optimal solutions in years with low
30
31 solar radiation intensity and less precipitation, respectively. The optimal solutions close to
32
33 Solution C tended to maximize the water storage (RSD), recommending it would be
34
35 adequate to implement floating PV deployment schemes and reservoir operation strategies
36
37 related to these optimal solutions in years with low solar radiation intensity and abundant
38
39 precipitation, respectively. Alternatively, the compromised solutions (Solution D in the
40
41 blue dotted circle) tended to make tradeoffs between two objectives, implying it would be
42
43 suitable to implement floating PV deployment schemes and reservoir operation strategies
44
45 related to these optimal solutions in years with moderate solar radiation intensity and
46
47 moderate precipitation, respectively.

2
3
4 Table 3 presented the optimal results of floating PV and hydropower output acquired
5 from the MOGOA in different seasons under the multiple-year scenario. As compared with
6 the non-optimization technique, the MOGOA not only increased the hydropower output
7 significantly but also raised the floating PV power output substantially. It was an interesting
8 finding that floating PV schemes associated with the MOGOA made considerable
9 improvements in seasonal power outputs, especially prominent in spring and summer.
10 Hydropower generation strategies corresponding to the MOGOA also produced
11 appreciable improvements in seasonal power outputs, especially noticeable in autumn and
12 winter. Taking Solution A for example, the improvement rates of the floating PV power
13 output not only reached 14.6% and 12.5% in autumn and winter accordingly but also
14 achieved as high as 21.8% and 20.2% in spring and summer accordingly. The improvement
15 rates of hydropower output attained 6.8% and 6.5% in spring and summer accordingly and
16 reached as much as 16.7% and 10.3% in autumn and winter accordingly. There are two
17 main reasons to achieve these outcomes. Despite that the floating PV is classified as non-
18 regulatable energy, the optimal tilt angle (α_t) schemes could effectively develop the
19 potential of solar power in four seasons and carve out a new niche for floating PV
20 deployment to overcome meteorological uncertainty. Besides, the optimal water release
21 strategies not only could prompt reservoir operation between flood season (summer) and
22 non-flood season (winter) to be complementary but also could spur on the complementarity
23 between hydropower and solar sources for reducing hydrological uncertainty. In addition,
24 considering Taiwan's energy prices in 2018, the MOGOA solution greatly improved the
25 average annual output of hydropower (10%) and floating PV (18.3%) as much as 91 million
26 USD/yr.

	Annual	254 (10.0)	242 (4.8)	248 (7.4)	252 (9.1)	231

^a Average seasonal power output of multiple years (2004-2019).

^b Multi-objective Grasshopper Optimization Algorithm.

^c A combination of simulation-based and Standard Operation Policy (SOP) approaches, where the simulation-based approach (i.e. Eq. (2) and the tilt angle $\alpha_t=0$) was adopted for calculating the floating PV output while the SOP-based approach (M-5 rule curves) was applied to estimating the outputs of water, food and hydropower.

^d Improvement rate (%), and the benchmark was the non-optimization technique.

Though the computation time step in this study was set as a ten-day period, Fig. 7 only presented the monthly tilt angle (α_t) results (= the average tilt angle of three ten-day periods). The reason for setting the time interval of the dynamic control on tilt angle as monthly time step, rather than a season or ten-day, was owing to making the tradeoff between the improvement in photoelectric conversion efficiency and the reduction in operation cost of floating PV deployment. Fig. 7 revealed the optimal tilt angle (α_t) schemes of floating PV deployment in four seasons in Taoyuan City. It was easy to observe that the maximal positive tilt angle appeared in winter (January, 44.3°) whereas the maximal negative tilt angle occurred in summer (July, -11.9°). Tilt angles in spring

Fig. 7. Optimal tilt angle (α_t) schemes of floating PV deployment in four seasons in Taoyuan City. Yellow arrow denotes the vertical solar radiation for gaining the maximum solar radiation intensity. E: East. S: South. W: West. N: North.

1
2
3
4 and summer were positive and varied between 10.6° and 31.2°. Each optimal monthly tilt
5
6 angle scheme aimed to maximize monthly photoelectric conversion efficiency through
7
8 pursuing the maximal duration of vertical solar radiation (yellow arrow in Fig. 7) coupled
9
10 with solar radiation intensity (i.e. different altitude angle, sun-earth distance and sunshine
11
12 duration).
13
14

15
16 To mitigate the impacts of uncertainties concerning installation site and PV type on
17
18 energy production cost in light of the Renewable Energy Statistics (2019) [22], production
19
20 profits, installation cost and maintenance cost were taken into account for calculating the
21
22 period of cost recovery in this study. The total installation cost of floating PV was
23
24 considered to be funded by a 10-year loan with an annual interest rate of 5% by local banks.
25
26 The annual maintenance cost was set as 3% of the initial cost of each floating PV panel
27
28 [47]. Moreover, the installation cost also took the impacts of the panel slopes (=tilt angle)
29
30 into account [19]. Based on production profits, installation cost and maintenance cost, the
31
32 period of cost recovery would reach 8 years (10 years) subject to a minimum of 25-year
33
34 (30-year) lifespan of floating PV. Under the optimal installed area-to-pond area ratio (40%)
35
36 of floating PV deployment, a recommendation was made to install a total installed capacity
37
38 of 992 MW ($= 12 \text{ (km}^2\text{)} * 40\% / (1.5 \text{ m}^2) * 310 \text{ (M)}$) sited in 740 ponds of Taoyuan City. Such
39
40 floating PV deployment would need a total installed cost of USD 942.4 million
41
42 ($= 992 * 950 / 1000$ million USD) while bring an average annual floating PV benefit ranging
43
44 between USD 66.3 million ($= 390 * 1000 \text{ MWh} * 170 \text{ USD/MWh}$) in Solution B and USD
45
46 74.8 million ($= 440 * 1000 \text{ MWh} * 170 \text{ USD/MWh}$) in Solution A (Table 2). For such cases
47
48 in accordance with current renewable energy prices, the floating PV costs would be
49
50 amortized over 8–10 years.

1
2
3
4 Despite the spatio-temporal heterogeneity of tilt angles, the reasons for this study to
5 consider only temporal heterogeneity are two-fold: the spatial heterogeneity [4313 MJ/m²
6 (megajoule), 4396 MJ/m²] of average annual solar radiation intensity over 740 irrigation
7 ponds (12 km² in area) is small; and the temporal heterogeneity [661 MJ/m² (Winter), 1508
8 MJ/m² (Summer)] of average seasonal solar radiation intensity in Taoyuan City is large.
9

10 11 12 13 14 15 16 17 18 **4.2 Synergy analysis of water-food-energy nexus**

19
20 Despite that there were 9 (=3*3) scenarios in combinations of hydrological (Dry, Normal,
21 and Wet years) and meteorological (High, Moderate, and Low solar radiation intensity)
22 conditions, three scenarios were specified to assess the impacts of hydrological and
23 meteorological uncertainties on synergetic benefits of the WFE nexus. S1 (Dry plus Low),
24 S2 (Normal plus Moderate), and S3 (Wet plus High) represent poor, moderate, and good
25 hydro-meteorological conditions, respectively.
26
27
28
29
30
31
32
33
34

35 Fig. 8 presented the synergetic benefits of the WFE nexus based upon the optimal
36 MOGOA solutions under scenarios S1, S2, and S3, where the non-optimization technique
37 (i.e. M-5 rule curves plus simulation-based) served as the benchmark. Though the MOGOA
38 solutions could effectively raise the synergetic benefits of the WFE nexus in all the three
39 scenarios, Solution A demonstrated to boost energy benefit greatly, Solution B
40 demonstrated to increase water storage highly, and Solution C demonstrated to improve
41 food production surpassingly. For instance, the cases upon Solutions (A, B, and C) under
42 the Wet plus High scenario (S3: wet year and high solar radiation intensity; orange color in
43 Fig. 8) would achieve the largest benefits: USD 93.9×10⁶ for APB (energy sector), 55% for
44 RWS (water sector), and 78×10⁶ kg for AFP (food sector). In addition, Solution D was

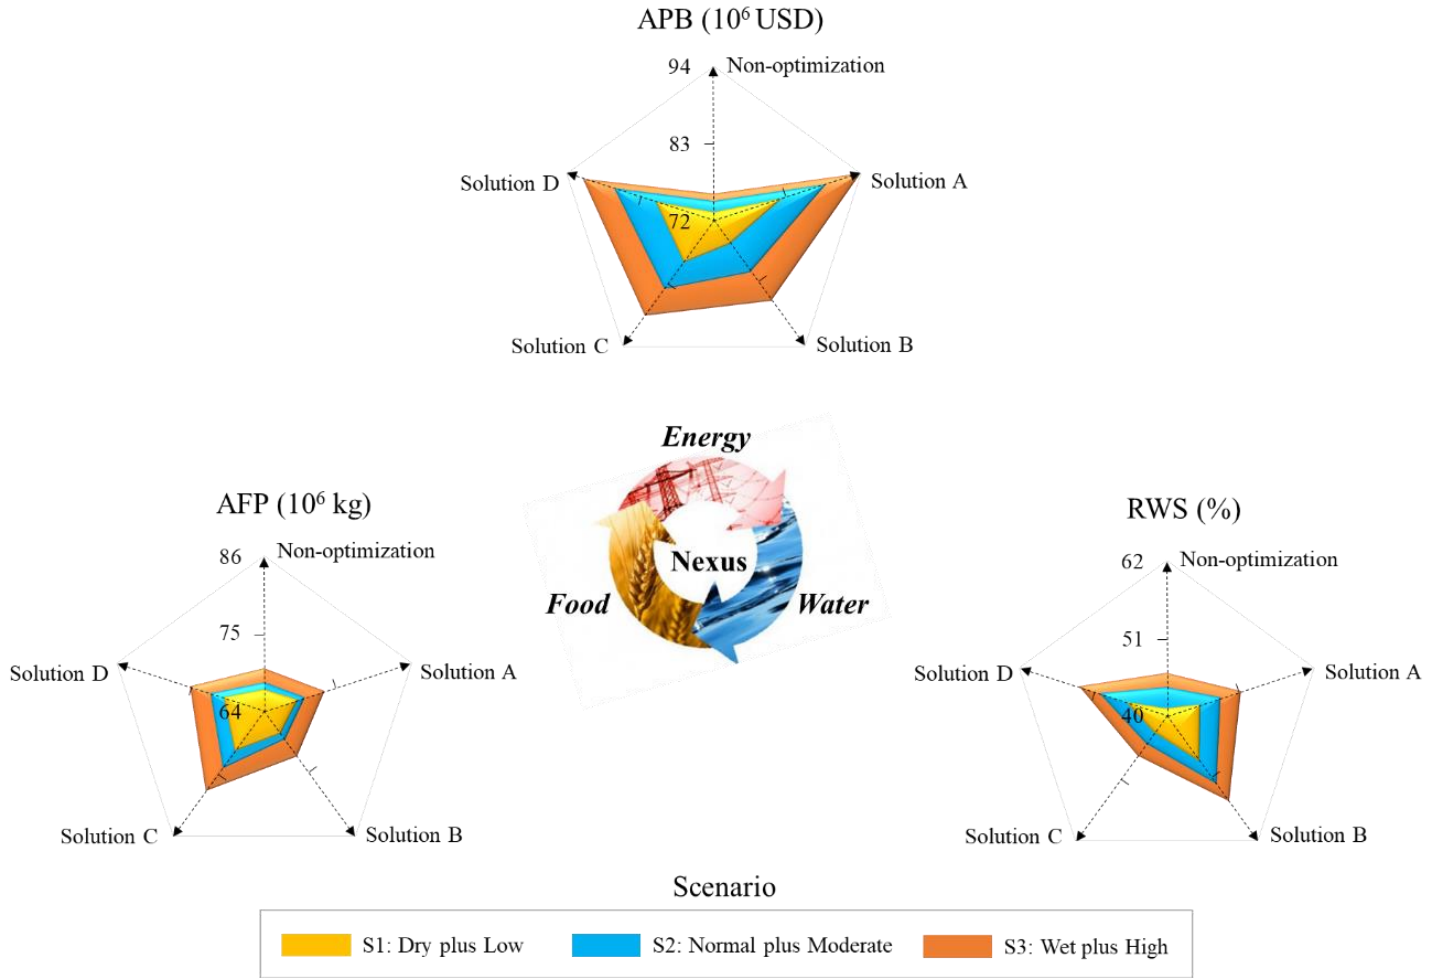

Fig. 8. Synergistic benefits of the WFE nexus based on the optimal MOGOA solutions (A, B, C, D) under three scenarios (S1, S2, S3). The non-optimization technique is the benchmark.

Scenario setting:

S1_Dry (Low) year: occurrence frequency of a dry year (low solar radiation intensity) was 80% (80%) during 2004 and 2019.

S2_Normal (Moderate) year: occurrence frequency a normal year (moderate solar radiation intensity) was 50% (50%) during 2004 and 2019.

S3_Wet (High) year: occurrence frequency of a wet year (high solar radiation intensity) was 20% (20%) during 2004 and 2019.

Hydrological (meteorological) year: starting from July to the next June in the study area.

Indicators of benefits:

APB (10⁶ in USD): average annual power benefits of floating PV (in Taoyuan City) and hydropower (Shihmen Hydropower Station). Purchase prices of solar power and hydropower were 170 USD/MWh and 67 USD/MWh accordingly.

RWS (%): average annual ratio of water storage to reservoir capacity in the Shihmen Reservoir.

AFP (10⁶ kg): average annual food production (including rice, vegetables, and fruits).

1
2
3
4 regarded as one of the compromised solutions and would hunt for the synergistic benefits
5
6 of three sectors at the same time, rather than the benefit of one sector only. It was obvious
7
8 that synergetic benefits were larger in the Wet plus High scenario (S3, orange color in Fig.
9
10 8) than in the Dry plus Low scenario (S1, yellow color in Fig. 8). It appeared that synergetic
11
12 benefits in relation to the three scenarios were, as expected, ranked as: S3 (Wet plus High,
13
14 orange) > S2 (Normal plus Moderate, blue) > S1 (Dry plus Low, yellow) (Fig. 8) than in
15
16 the scenario (S1, color in Fig. 8). These findings greatly support the importance of water
17
18 availability (hydrological condition) and solar radiation intensity (meteorological condition)
19
20 to boosting the synergetic benefits of the WFE nexus.
21
22
23
24
25

26 Table 4 summarized the improvement rate corresponding to the synergies of the WFE
27
28 nexus created by the MOGOA solutions under the three scenarios, where the non-
29
30 optimization technique served as the benchmark. The results of the solution completely
31
32 dominated by PHO (Solution A) disclosed that the improvement rates of water storage
33
34 (RWS) were 10.9% in the Wet plus High scenario (S3) and 7.9% in the Dry plus Low
35
36 scenario (S1), the improvement rates of food production (AFP) were 6.3% in S3 and 3.3%
37
38 in S1, and the improvement rates of food production (APB) reached 23.7% in S3 and 12.3%
39
40 in S1. Accordingly the energy benefits (APB) achieved USD 93.9×10^6 in S3 and USD
41
42 82.23×10^6 in S1 (Fig. 8). These outcomes indicated that Solution A would substantially
43
44 raise much more energy output (hydropower and floating PV) in the Wet plus High scenario
45
46 (S3) than in the Dry plus Low scenario (S1). Similarly, Solution B (RWS fully dominates)
47
48 and Solution C (RSD fully dominates) would significantly drive up more water storage
49
50 (improvement rate = 19.6%) and more food production (improvement rate = 11.4%) in the
51
52 Wet plus High scenario (S3), as compared with those
53
54
55
56
57
58
59
60
61
62
63
64
65

Table 4 Improvement rates concerning the synergistic benefits of the WFE nexus attained from the MOGOA solutions under three scenarios. The non-optimization technique served as the benchmark.

Solution (obtained from MOGOA)	Nexus	Indicator	Scenario		
			S1 Dry plus Low ^e	S2 Normal plus Moderate ^f	S3 Wet plus High ^g
Solution A (PHO ^d fully dominates)	Water	RWS ^a	7.9 ^h	9.8	10.9
	Food	AFP ^b	3.3	4.9	6.3
	Energy	APB ^c	12.3	18.6	23.7
Solution B (RWS fully dominates)	Water	RWS	16.1	18.2	19.6
	Food	AFP	2.2	3.5	4.9
	Energy	APB	3.7	8.1	13.3
Solution C (RSD fully dominates)	Water	RWS	2.9	3.3	5.9
	Food	AFP	6.0	8.8	11.4
	Energy	APB	8.1	12.1	16.6
Solution D (compromised)	Water	RWS	10.2	13.6	15.2
	Food	AFP	5.5	6.9	8.1
	Energy	APB	10.1	16.0	20.5

^a average annual ratio of water storage to reservoir capacity in the Shihmen Reservoir.

^b average annual food production (including rice, vegetables, and fruits).

^c average annual power benefits of the floating PV (Taoyuan City) and hydropower (Shihmen Hydropower Station).

^d average annual floating PV and hydropower output.

^e S1_Dry (Low) year: occurrence frequency of a dry year (low solar radiation intensity) was 80% (80%) during 2004 and 2019.

^f S2_Normal (Moderate) year: occurrence frequency a normal year (moderate solar radiation intensity) was 50% (50%) during 2004 and 2019.

^g S3_Wet (High) year: occurrence frequency of a wet year (high solar radiation intensity) was 20% (20%) during 2004 and 2019.

^h Improvement rate (%), and the benchmark was the non-optimization technique.

of the Dry plus Low scenario (S1). This again demonstrated the significance of water availability and solar radiation intensity in stimulating the synergetic benefits of the WFE nexus. Furthermore, the results of Solution D pointed out that the complementary generation of hydropower (reservoir) and floating PV deployment (pond) in the Normal plus Moderate scenario (S2) could promote the water storage by as much as 13.6% (water

1
2
3
4 sector), raise food production by up to 6.9% (food sector), and run up the benefit of
5
6 hydropower and floating PV by USD 86.81 million (Fig. 8), with an improvement rate of
7
8 16% (power sector). Although Solution D was a compromised solution, its high
9
10 achievement in energy sectors could be accredited to the complementary collaboration
11
12 between hydropower operation and floating PV deployment.
13
14

15
16 Table 5 presented the improvement rates concerning the synergies of the WFE nexus
17
18 created by the MOGOA solutions, considering the impacts of the respective weights of the
19
20 three objects (PHO, RWS, and RSD) based on the long-term complementary operation
21
22 strategy under three scenarios. The non-optimization technique served as the benchmark.
23
24 The weights of three objects not only disclosed the preference of decision-makers but also
25
26 indicated the improvement rates corresponding to the synergies of the WFE nexus, where
27
28 a larger weight would create a larger improvement rate. For instance, the largest
29
30 improvement rate was created by the energy production with the largest weight in Solution
31
32 1 under all cases, meanwhile, similar phenomena appeared in Solutions 2-4. The results
33
34 suggested with various favorable nexus solutions that decision-makers could experience
35
36 potential outcomes (benefits) to make ambitious (or conservative) nexus strategies in
37
38 response to challenges encountered in water, food and energy sectors under different
39
40 scenarios.
41
42
43
44
45
46
47

48 In sum, the proposed MOGAO methodology aimed at exploring the collaboration
49
50 between floating PV deployment on irrigation ponds and hydropower (reservoir) operation
51
52 to spur on WFE nexus synergies, in comparison to the non-optimization technique. Water
53
54 shortages threatening public and irrigation sectors appeared to be ameliorated by means of
55
56 optimizing reservoir operation through a tradeoff between
57
58
59
60
61
62
63
64
65

Table 5 Improvement rates concerning the synergies of the WFE nexus created by the MOGOA solutions, which considered the impacts of the respective weights of three objects on the WFE nexus based on the long-term complementary operation strategy under three scenarios. The non-optimization technique served as the benchmark.

Solution (obtained from MOGOA)	Nexus (Weight ^a)	Indicator	Scenario		
			S1 Dry plus Low	S2 Normal plus Moderate	S3 Wet plus High
Solution 1: Benefit to PHO	Water (0.20)	RWS	4.9 ^b	6.4	8.4
	Food (0.20)	AFP	4.5	5.9	7.8
	Energy (0.60)	APB	10.1	14.3	18.5
Solution 2: Benefit to RWS	Water (0.60)	RWS	11.7	14.8	17.2
	Food (0.20)	AFP	4.7	6.1	7.7
	Energy (0.20)	APB	5.4	6.5	8.1
Solution 3: Benefit to RSD	Water (0.20)	RWS	3.5	5.7	7.4
	Food (0.60)	AFP	5.7	8.3	10.9
	Energy (0.20)	APB	4.9	6.9	9.5
Solution 4: Compromised	Water (0.33)	RWS	5.4	9.1	12.1
	Food (0.33)	AFP	5.1	6.5	8.6
	Energy (0.34)	APB	7.2	9.5	14.2

^a Weights were calculated using the standardization values of three objects (PHO, RWS, and RSD) created by the MOGOA solutions. The sum of the respective weights of three objects was equal to one.

^b Improvement rate (%), and the benchmark was the non-optimization technique.

reservoir storage and water supply while insufficient energy production endangering urbanization development could be improved through the joint optimization of floating PV deployment and hydropower generation. The diverse MOGOA solutions could simultaneously optimize the synergetic benefits of traditional reservoir impoundment, water supply, as well as hydropower output regulated by SOP (M-5 rule curves) and solar power output from floating PV deployment. The RWS was improved by 4.3% up to 13%, the RSD by 3.6% up to 13%, and the PHO by 4.8% up to 15.1% under the multiple-year scenario (Table 1). With the optimal solutions on hand, decision-makers could reasonably select appropriate strategies to deal with various meteorological and hydrological

1
2
3
4 conditions faced for effectively managing the intensive conflicts among energy, food and
5
6 water demanding sectors. Additionally, for a total irrigation pond area of roughly 12 km²
7
8 (740 ponds) in Taoyuan City of Taiwan, the potential installed capacity (MW) would reach
9
10 as high as 992 MW if each of the 740 ponds could be deployed a floating PV system over
11
12 40% of the pond area based on an assumption of homogeneous solar radiation intensity in
13
14 Taoyuan City.

17
18
19
20

21 **5. Conclusions**

22
23 This study conducted a holistic assessment on the prospect for long-term complementary
24
25 operation between floating photovoltaic and hydropower generation in the interest of
26
27 cleaner energy development for improving water-food-energy nexus synergies by
28
29 exploring a MOGOA-based approach. The hydropower reservoir operation based on M-5
30
31 rule curves and floating photovoltaic deployment using horizontal installation (tilt angle =
32
33 0°) served as the benchmark (non-optimization approach). The main conclusions were
34
35 drawn as follows.
36
37
38
39

40
41 The optimal solutions under the multiple-year scenario demonstrated the average
42
43 annual ratio of water storage to reservoir capacity achieved as much as 52%, the average
44
45 annual food production came up with 74 million kg (corresponding to the ratio of water
46
47 supply to water demand = 94%), and the average hydropower and floating photovoltaic
48
49 output reached as high as 694 million kWh. The maximal improvement rates of the
50
51 MOGOA-based approach could reach 13%, 13.3% and 15.1% in water storage, food
52
53 production and energy output, respectively, as compared to the benchmark. The optimal tilt
54
55 angles of floating photovoltaic installation would vary between -11.9° (Summer) and 44.3°
56
57
58
59
60
61
62
63
64
65

1
2
3
4 (Winter). The deployment of floating photovoltaic systems over 740 ponds would lead to
5
6 a total installed capacity of 992 MW and a total installed cost of USD 942.4 million while
7
8 the average annual output benefit would vary between USD 66.3 million and USD 74.8
9
10 million under the multiple-year scenario. The period of cost recovery for floating
11
12 photovoltaic deployment would be 8-10 years once energy production starts. Furthermore,
13
14 the complementary collaboration between floating photovoltaic and hydropower
15
16 generation would make the average annual energy benefit reach high up to USD 91 million.
17
18
19
20

21 This study not only initiates effective actions on hydro-floating photovoltaic power
22
23 operation to promote water-food-energy nexus synergies but also innovating practical
24
25 solutions to renewable energy exploitation in the best interest of friendly environment and
26
27 social sustainability. Future research can consider assessing more mutual benefits (e.g.
28
29 carbon dioxide emission reduction and land conservation) driven by floating photovoltaic
30
31 deployment at a global or national scale, apart from water-food-energy synergies.
